# Types and Definitions

The following is the list of allowed data types and their descriptions:

| Type   | Description                                                               | Accepted Input (from TCL)                                                                                                                                                                                                                       | Output Format (to TCL)                                                                                     |
|--------|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| bool   | A boolean value.                                                          | true: true/1/on/yes<br>false: false/0/off/no                                                                                                                                                                                                    | true or false                                                                                              |
| int    | Signed 32-bit integer corresponding to Tcl integer.                       | Any integer value.                                                                                                                                                                                                                              | 26                                                                                                         |
| double | Double-precision (64-bit) signed float.                                   | Any numeric value.                                                                                                                                                                                                                              | 26.4<br>A .0 is added to the output of integer values to force it to be a double (e.g. 1.0 rather than 1). |
| string | A string. Unlike other types, the empty string is a valid value.          | Any Tcl string value, like "abc" or {abc}.                                                                                                                                                                                                      | abc                                                                                                        |
| enum   | One of a fixed set of string values (provided in the type qualification). | If "true" or "false" are enum values, these are interpreted as booleans.<br>For example: enum (true false auto) accepts<br>- "0", "no" and "off" as synonyms for "false"<br>- "1", "yes" and "on" as synonyms for "true"<br>- "auto" for "auto" | auto                                                                                                       |

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| obj      | <p>A database object pointer. It is followed by the list of object types allowed for this attribute. It is optionally followed by</p> <ul style="list-style-type: none"> <li>* object list of 0 or more</li> <li>+ object list of 1 or more</li> <li>? object link may be empty</li> </ul> <p>For example, obj(inst hinst)+ is a list of 1 or more inst or hinst objects. A mixture of both inst and hinst objects is possible.</p> | <p>A dual-ported Tcl object or object list. The string form for netlist objects is &lt;obj_type&gt;:<br/>&lt;design_name&gt;/&lt;object_name&gt;, for example:</p> <p>inst:my_design/i1/i2</p> <p>For technology or library objects it is just &lt;obj_type&gt;:&lt;name&gt;, for example:</p> <p>layer:metal1</p> <p>For objects with no useful name (like a wire), it is just the hex memory pointer, for example:</p> <p>wire:0x123300012</p> <p>Type "man get_db" for more details on dual-ported Tcl objects.</p> | <p>layer:metal1</p> <p>inst:my_design/i1/i2</p> <p>wire:0x123300012</p>                                               |
| in_file  | A file name that will be read in.                                                                                                                                                                                                                                                                                                                                                                                                   | A Unix path name (relative or absolute). The file must exist and be readable.                                                                                                                                                                                                                                                                                                                                                                                                                                          | my_dir/myfile.tcl                                                                                                     |
| out_file | A file that will be written to.                                                                                                                                                                                                                                                                                                                                                                                                     | A Unix path name (relative or absolute). The file must be writable.                                                                                                                                                                                                                                                                                                                                                                                                                                                    | my_dir/my_file.tcl                                                                                                    |
| in_dir   | A directory to read from.                                                                                                                                                                                                                                                                                                                                                                                                           | A Unix path name (relative or absolute). The directory must exist and be readable.                                                                                                                                                                                                                                                                                                                                                                                                                                     | my_dir                                                                                                                |
| out_dir  | A directory to write into.                                                                                                                                                                                                                                                                                                                                                                                                          | A Unix path name (relative or absolute). The directory must be writable.                                                                                                                                                                                                                                                                                                                                                                                                                                               | my_dir                                                                                                                |
| coord    | A single, linear distance in microns that type double..                                                                                                                                                                                                                                                                                                                                                                             | Any numerical value in units of microns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <p>26.4</p> <p>A .0 is added to the output of integer values to force it to be a double (e.g. 1.0 rather than 1).</p> |

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                 |                                             |

## analysis\_view

### Parent Objects

[design](#), [root](#)

### Definition

An analysis view binds together a constraint mode with a delay corner, providing all the information needed to control a single MMMC analysis. Use the `create_analysis_view` and `update_analysis_view` commands to create and modify analysis\_views.

| Attribute       | Description                                                                                                                                                          |

All the LEF CLASS and PROPERTY LEF58\_CLASS values (and equivalent OpenAccess values). Refer to the LEF documentation for the complete list and descriptions. They are separated into 5 classes with a unique prefix based on their usage as described here:

CLASS COVER types all start with cover.

CLASS RING or BLOCK start with block.

CLASS PAD start with pad.

CLASS CORE start with core.

CLASS ENDCAP that are corner cells (TOPLEFT, TOPRIGHT, BOTTOMLEFT, BOTTOMRIGHT) start with corner.

CLASS ENDCAP that are not corner cells all start with core because they are all placed in the core rows like CLASS CORE cells.

No CLASS means the value is none.

Modifications are valid only for the current session.

**Default:** ""

**Edit:** Yes

## cts\_cell\_halo\_x

Specifies the clock halo distance in the x direction. The default value of this attribute is auto.

The following attributes can be used to assign x direction clock halos within CCOpt:

cts\_cell\_halo\_x

cts\_cell\_density

cts\_cell\_halo\_sites

Only one of these attributes is used to determine the clock halo in the x direction. The following rules determine which:

. If cts\_cell\_halo\_x is set to a non-auto value, then this defines the x direction clock halo. The attributes cts\_cell\_density and cts\_cell\_halo\_sites have no effect.

. If cts\_cell\_halo\_x is set to auto and cts\_cell\_density is set to a non-auto value then cts\_cell\_density defines the clock halo in the x direction. The attribute cts\_cell\_halo\_sites has no effect.

. If both cts\_cell\_halo\_x and cts\_cell\_density are set to auto then cts\_cell\_halo\_sites defines the clock halo in the x direction.

Clock tree definition will, by default, not continue through certain types of cell arc (for instance, the clock to Q arc in a DFF). This attribute allows you to override this default behavior, permitting the clock tree to trace through all instances of such a cell.

This attribute serves the same function as `trace_through_to`, except that here the clock path is specified at the level of the library cell.

The attribute should be configured on the input library pin at which the clock will arrive. The value of the attribute specifies the output library pin to which the clock should propagate. The specified output pin must be another pin on the same library cell. The output pin may be specified either by its fully qualified name (i.e. inclusive of the cell name), or else simply by its local (cell-relative) name.

There must be a pre-existing (library-defined) chain of one or more delay arcs that connect the input and output pins together. It is not possible to use `library_trace_through_to` to synthesize delay arcs.

If multiple input pins are annotated on a given library cell, the value of `library_trace_through_to` at each of those pins must select the same output pin: i.e. the configuration must identify a single clock output for the cell. If multiple clock outputs are necessary then `library_trace_through_to` should not be used: instead for each instance of the library cell, define a generated clock tree at each of the clock-carrying outputs.

If the configuration of `library_trace_through_to` settings for a given library cell does not meet these requirements, a warning will be issued and the settings for that cell will be ignored.

All instances of the library cell will be affected by this setting. If both `trace_through_to` and `library_trace_through_to` are applicable at a given instance pin, the `trace_through_to` value will take precedence.

Valid values: `base_pin`

**Type:** `string`  
**Default:** `""`  
**Edit:** Yes

`cts_stack_via_rule`

|                          | <p>Base_pins's direction from .lib if available, otherwise from LEF/OA. It can be in, out, inout or internal. Internal means it is an internal pin from a .lib file for the timing model, and is not part of the netlist. If there is no .lib for this cell, then the direction comes from the LEF PIN DIRECTION or equivalent OA oaTermType. The LEF DIRECTION values (and equivalent oaTermType values) are mapped this way: INPUT = in, OUTPUT = out, OUTPUT TRISTATE = out, INOUT = inout, FEEDTHRU = inout, and the oaTermType unknown = inout.</p> <p><b>Type:</b> <a href="#">enum</a><br/> <b>Enum Values:</b> in out inout internal<br/> <b>Default:</b> ""<br/> <b>Edit:</b> No</p> |

Indicates how this pin is used from the LEF USE value or OA equivalent. The legal values are: signal analog power ground clock. Note that timing analysis does not use these values, it uses the .lib data instead (e.g. is\_clock, is\_analog, etc.). So the signal, clock or analog values are not normally used by applications. The power/ground values are used by many applications.

**Type:** [enum](#)

**Enum Values:** signal analog power ground clock

**Default:** ""

**Edit:** No

## boundary

### Parent Objects

[hinst](#), [design](#), [root](#)

### Definition

A boundary object can only be attached to an hinst, normally when the hinst is a partition. It is used to constrain the placement of all the insts of the hinst. See the group object for placement constraint information attached to the group object (e.g. a list of insts, hinsts, or groups).

| Attribute | Description                                                                                                                          |

The type of bus\_guide.  
hard: Specifies the bus\_guide as a hard constraint for routing. eGR, NR and NRHF should obey the path of bus guide.  
soft: Specifies the bus\_guide as a soft constraint for routing. eGR, NR and NRHF should be guided by the route path. But tool can route the net out of the bus guide.  
**Type:** [enum](#)  
**Enum Values:** soft hard  
**Default:** ""  
**Edit:** Yes

## bus\_sink\_group

### Parent Objects

[design](#), [root](#)

### Definition

A group of sinks (loads) that some floorplan and routing commands use to control adding buffers and routing for a bus. See 'help \*bus\_sink\*' for a list of commands related to this object.

Specifies the clock halo in the x direction.  
Any x direction clock halo defined by this attribute is proportional to the cell width.  
The constant of proportionality is defined by the attribute value. For example:  
. If `cts_cell_density` = 0.25 then the x direction clock halo equals 3 \* cell width.  
. If `cts_cell_density` = 0.5 then the x direction clock halo equals cell width.  
. If `cts_cell_density` = 0.75 then the x direction clock halo equals cell width / 3.  
. If `cts_cell_density` = 1 then the x direction clock halo equals zero.  
This attribute can specify the x direction clock halo for all clock trees via:  
`set_db cts_cell_density 0.8`  
This attribute can specify the x direction clock halo per-clock tree via:  
`set_db clock_tree:<clk> .cts_cell_density 0.9`  
The following attributes can be used to assign x direction clock halos within CCOpt:  
`cts_cell_halo_x`  
`cts_cell_density`  
`cts_cell_halo_sites`  
Only one of these attributes is used to determine the clock halo in the x direction. The following rules determine which:  
. If `cts_cell_halo_x` is set to a non-auto value, then this defines the x direction clock halo. The attributes `cts_cell_density` and `cts_cell_halo_sites` have no effect.  
. If `cts_cell_halo_x` is set to auto and `cts_cell_density` is set to a non-auto value then `cts_cell_density` defines the clock halo in the x direction. The attribute `cts_cell_halo_sites` has no effect.  
. If both `cts_cell_halo_x` and `cts_cell_density` are set to auto then `cts_cell_halo_sites` defines the clock halo in the x direction.  
Valid values: 0.01 to 1

. `cts_cell_halo_sites`  
**Type:** [string](#)  
**Default:** 0.75  
**Edit:** Yes

`cts_cell_halo_x`

Specifies the clock halo distance in the x direction. The default value of this attribute is auto.

The following attributes can be used to assign x direction clock halos within CCOpt:

- cts\_cell\_halo\_x
- cts\_cell\_density
- cts\_cell\_halo\_sites

Only one of these attributes is used to determine the clock halo in the x direction. The following rules determine which:

- . If cts\_cell\_halo\_x is set to a non-auto value, then this defines the x direction clock halo. The attributes cts\_cell\_density and cts\_cell\_halo\_sites have no effect.
- . If cts\_cell\_halo\_x is set to auto and cts\_cell\_density is set to a non-auto value then cts\_cell\_density defines the clock halo in the x direction. The attribute cts\_cell\_halo\_sites has no effect.
- . If both cts\_cell\_halo\_x and cts\_cell\_density are set to auto then cts\_cell\_halo\_sites defines the clock halo in the x direction.

## constraint\_mode

### Parent Objects

[analysis\\_view](#), [design](#), [root](#)

### Definition

Associates a list of SDC constraint files with a specified constraint mode name, for multi-mode multi-corner analysis. This constraint mode name can be referred to later when creating analysis views. Use the `create_constraint_mode` and `update_constraint_mode` commands to create and modify constraint\_modes.

| Attribute     | Description                                                                                                                                                                                            |

## def\_scan\_chain

### Parent Objects

[design](#), [root](#)

### Definition

A single scan-chain equivalent to one DEF SCANCHAIN. It is used by the placer to reorder scan-chain elements to reduce routing and congestion.

| Attribute      | Description                                                                                                                                                                                                                                                                               |

## delay\_corner

### Parent Objects

[analysis\\_view](#), [design](#), [root](#)

### Definition

The delay\_corner object provides references to rc\_corner objects which define the interconnect corner and timing\_condition-to-domain bindings which define device operating corners - providing the majority of the configuration information needed to drive delay calculation. An analysis\_view object will reference the delay\_corner and combine it with a constraint\_mode to complete the configuration. Use the create\_delay\_corner and update\_delay\_corner commands to create and modify delay\_corner objects.

|                                                 | <p>Controls the omission of symmetry features to balance a flexible H-tree.</p> <p>Symmetry drivers are drivers that are added to balance pin capacitances at branch points. For example, if buffer pairs are inserted at branch points, one of these buffers may not drive any fanout and is inserted to match other buffer pairs at the same level of the flexible H-tree. Omitting symmetry drivers can reduce the power of the H-tree but increase its skew. Drivers that are added to terminate symmetry branches (see below) do not count as symmetry drivers and are never omitted.</p> <p>Similarly, symmetry branches are branches that are needed to balance the wire load at branch points. They are added to match other branchpoints at the same level of the flexible H-tree. Symmetry branches are always terminated with drivers, which are not counted as symmetry drivers.</p> <p>By default, symmetry branches and drivers are added.</p> <p>Possible values for this attribute:</p> <p>false Add symmetry branches and drivers</p> <p>true Omit both symmetry drivers and branches</p> <p>drivers Omit symmetry drivers</p> <p>branches Omit symmetry branches</p> <p>{drivers branches} Omit both symmetry drivers and branches</p> <p>{ } Add symmetry branches and drivers</p> <p><b>Type:</b> <a href="#">string</a></p> <p><b>Default:</b> auto</p> <p><b>Edit:</b> Yes</p> |

|                                 | <p>The groups in which partition are clustered in channelless designs. Nested lists imply allowed crossings between groups. Each group has zero or one input port and each partition must only be specified once.</p> <p>Optionally, a maximum pre-route net length from the boundary of a partition group can be specified. This argument must be specified as the second parameter of a nested partition group.</p> <p>Optionally, the next argument specifies the clock phase when entering the partition group in relation to the root pin of the H-tree. Allowed values are 'inverting' and 'non-inverting'. If no value is specified, the clock phase is unconstrained. The clock phase is unconstrained when crossing the boundaries of partitions within the same group. All specified clock phases must be either inverting or non-inverting.</p> <p>Example:<br/> <pre>{{A} {{C D} 50 non_inverting {{E F}} {{G}}}}</pre> </p> <ul style="list-style-type: none"> <li>- The H-tree starts in partition A and descends into group C/D.</li> <li>- From partition group C/D, the tree descends into groups E/F and G.</li> <li>- Any clustering of sinks inside the C/D and E/F groups are allowed, potentially crossing internal partition boundaries several times.</li> <li>- Partition A has no clock input port and one clock output port</li> <li>- Partition group C/D has one clock input port and two clock output ports</li> <li>- Partition group E/F and G have one clock input port and no clock output port</li> <li>- The maximum net length from the entry point into partition group C/D is 50um (pre-route)</li> <li>- The clock phase is non-inverting when entering partition group C/D. The clock phase is unconstrained when entering other partition groups.</li> </ul> <p>Valid values: string<br/> <b>Type:</b> string<br/> <b>Default:</b> ""<br/> <b>Edit:</b> Yes</p> |

|                                  | <p>Specifies the columns and rows of a grid of H-tree sinks, where the columns and rows may be swapped if the cts_flexible_htree_adjust_sink_grid_for_aspect_ratio attribute is true.</p> <p>If using synthesize_flexible_htrees -partition the sink grids may be specified for each partition. If only some partitions have specified sink grids, then for the other partitions the sink grid will be inferred from the floorplan sink grid. To specify a sink grid for the top-level outside partitions, the design name is used. The cts_flexible_htree_adjust_sink_grid_for_aspect_ratio attribute is not applied to partition-based sink grids.</p> <p>Example:</p> <p>For an H-Tree spanning partitions A, B, C and the top_cell a sink grid of { 8 8 { hinst:A 2 1 } { hinst:B 2 2 } { design:top 8 2 } } means that partition A will have 2x1 grid, partition B will have a 2x2 grid, the top-level will have an 8x2 grid and the grid for partition C will be inferred from its size and the 8x8 floorplan grid.</p> <p>To achieve a low global skew of the flexible H-tree and avoid balancing induced detours, the pitch between H-tree sinks in all partitions and in the top level should be similar. This can be achieved by aligning the number of columns and rows with the dimensions of the partitions and adjusting the bounding box of the sink grids using the cts_flexible_htree_sink_grid_box attribute. It may also be beneficial to exclude isolated H-tree sinks by reducing the sink grid box of a partition if the sinks are not critical for timing purposes.</p> <p>Valid values: {[columns rows] [{partition_hinst design columns rows}]...}</p> <p><b>Type:</b> string</p> <p><b>Default:</b> ""</p> <p><b>Edit:</b> Yes</p> |

|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                              | <p>The box describing the area that the grid of H-tree sinks should cover. This attribute only has an effect if the <code>cts_flexible_htree_sink_grid</code> attribute of the flexible H-tree is set.</p> <p>If using <code>synthesize_flexible_htrees</code> -partition the sink grid boxes may be specified for each partition. The tool will use the intersection of the specified partition box with the bounding box of the partition area. If a floorplan box is used, the box for partitions without a specified box will be the intersection of the floorplan box and the partition boundary. To specify a sink grid box for the top-level, the design name is used.</p> <p>Example:<br/>For an H-Tree spanning partitions A, B, C and the top-level a sink grid of { { hinst:A 0 600 500 800 } { hinst:B 600 700 1000 1000 } { design:top 0 0 1000 500 } } means that the sink grid for partition A will cover the box {0 600 500 800}, partition B will cover {600 700 1000 1000}, top-level will cover {0 0 1000 500} and the grid for partition C will cover the whole partition.</p> <p>Valid values: {[xmin ymin xmax ymax] [{partition_hinst design xmin ymin xmax ymax}]...}</p> <p><b>Type:</b> string<br/><b>Default:</b> ""<br/><b>Edit:</b> Yes</p> |

# gcell

## Parent Objects

[design](#), [root](#)

## Definition

A global-routing cell. It only exists after global routing has been run, and includes the number of routing tracks available (supply), and the tracks used (demand) for each gcell.

| Attribute            | Description                                                                                                                                                                                                                                                |

## dont\_touch

This attribute defines the user preservation status of the hinst during optimization. Setting this attribute will set the dont\_touch attribute on the parent module of this hinst and all hinsts of same module. This setting will apply to all insts within the hinst unless overridden at a lower hinst or on the inst object itself. The dont\_touch\_effective attribute on each child inst and hinst return the resolved value.

Use 'help inst dont\_touch' to see the enum value definitions but note that map\_size\_ok is not allowed at the instance level.

**Type:** enum

**Enum Values:** none false true delete\_ok const\_prop\_size\_delete\_ok const\_prop\_delete\_size\_delete\_ok size\_ok size\_same\_height\_ok size\_same\_footprint\_ok

**Default:** none

**Edit:** Yes

## dont\_touch\_effective

This attribute defines the effective preservation status of this hinst during optimization from the dont\_touch\_sources values. If the partition source is 'true' or the ilm source is 'true', then the effective value for the hinst is 'true'. Otherwise, the user value has precedence. If the user value is false, then the parent value is returned.

See help on inst dont\_touch attribute for details on possible values.

**Type:** enum

**Enum Values:** none false true delete\_ok const\_prop\_size\_delete\_ok const\_prop\_delete\_size\_delete\_ok size\_ok size\_same\_height\_ok size\_same\_footprint\_ok

**Default:** false

**Edit:** No

## dont\_touch\_file

Specifies the sourced file to set dont\_touch.

**Type:** string

**Default:** ""

**Edit:** Yes

## dont\_touch\_hports

|                          | <p>The same as .escaped_name without any \ escape chars. This name is commonly used to : problems with \ escape chars in Tcl scripts unless you carefully use list operators. Like SDC commands, 'get_db insts i1/i2' will first try to match i1/i2, and if not found then match i1\i2 so flattening hierarchical names (e.g. with ungroup) does not require changing the names in T scripts.</p> <p><b>Type:</b> <a href="#">string</a><br/> <b>Default:</b> ""<br/> <b>Edit:</b> No</p> |

|                         | <p>The same as .escaped_name without any \ escape chars. This name is commonly used to avoid problems with \ escape chars in Tcl scripts unless you carefully use list operators. Like SDC commands, 'get_db insts i1/i2' will first try to match i1/i2, and if not found then match i1\i2 so that flattening hierarchical names (e.g. with ungroup) does not require changing the names in Tcl scripts.</p> <p><b>Type:</b> <a href="#">string</a><br/> <b>Default:</b> ""<br/> <b>Edit:</b> No</p> |

|                | <p>The same as .escaped_name without any \ escape chars. This name is commonly used to avoid problems with \ escape chars in Tcl scripts unless you carefully use list operators. Like SDC commands, 'get_db insts i1/i2' will first try to match i1/i2, and if not found then match i1\i2 so flattening hierarchical names (e.g. with ungroup) does not require changing the names in Tcl scripts.</p> <p><b>Type:</b> <a href="#">string</a><br/> <b>Default:</b> ""<br/> <b>Edit:</b> No</p> |

|                              | <p>A list of reasons to explain why the inst could not be cloned.</p> <p>This attribute will not be set if attributes cts_clone_clock_gates/cts_clone_clock_logic are</p> <p>The attribute returns a list of reasons why the inst cannot be cloned.</p> <p>The reasons why a inst cannot be cloned can be divided into three categories:</p> <ol style="list-style-type: none"> <li>1. The inst is marked as dont_touch</li> </ol> |

2. Reasons specific to the clock node

3. General reasons

The possible dont\_touch reasons are:

dont\_touch.add\_port\_driver Set if inst was added above an output port or below an input port  
attribute cts\_add\_port\_driver

dont\_touch.add\_driver\_cell Set if inst was added below the root via attribute cts\_add\_driver

dont\_touch.clock\_root Set during clock tree extraction if identified as having the root pin

dont\_touch.clock\_sink Set on inst if any pin is a clock sink in a clock tree

dont\_touch.clock\_tree\_generator\_path Set if nodes and wires are in clock tree generator

dont\_touch.clock\_wire Set on inst if clock input wire is user dont\_touch

dont\_touch.clockgate\_no\_power\_domain Set if clock gate / clock logic is a clocknode in a clock gate / clock logic power domain

dont\_touch.drives\_multi\_driver\_net Set if inst drives wires with other drivers

dont\_touch.external\_skew\_group\_pin Set if a pin on the inst is a skew group sink, source or  
ignore pin for a skew group created by the user

dont\_touch.flexible\_htree Set if inst was added to a flexible H-tree

dont\_touch.internal\_skew\_group\_pin Set if a pin on the inst is a skew group sink, source or  
pin for a skew group created by CCOpt

dont\_touch.neg\_edge\_clock\_gate Set if a clock gate gates the falling edge

dont\_touch.non\_flop\_clock\_gating Set during CTS on insts where cloning them could cause  
non-equivalence failure in LEC, including clock gates whose transitive fanout contains flop  
triggered by the opposite clock edge, macros, or latches

dont\_touch.non\_standard\_inputs\_clock\_gate Set if inst is a clock gate with 'non-standard'  
to avoid disconnecting them

dont\_touch.observability\_clock\_gate Set if inst is a clock gate with an observability output

dont\_touch.output\_wire Set if inst drives a net that is dont\_touch

dont\_touch.placer.lock Set if inst is user locked or locked by DEF

dont\_touch.power\_management Set if inst is a power management inst

dont\_touch.prevent\_assign Set if inst is necessary to prevent an assign

dont\_touch.sdc Set if constrained by SDC timing

dont\_touch.sdc\_path\_group Set if there is an SDC path group start / endpoint on one of the  
this inst

dont\_touch.sub\_block Set if inst is in dont\_touch module

dont\_touch.unmergeable\_composite\_clock\_gate Set if some of the clock gate is dont\_touch

dont\_touch.user Set by user

Contact Cadence Support if any of the following reasons are listed:

dont\_touch.cannot\_understand\_clock\_gate Set if clock gate not recognized

dont\_touch.composite\_clock\_gate\_enable\_test\_or\_gate

The possible reasons specific to the clock node are:

PowerManagement Set if inst is a power management inst

PowerManagementInconsistency Set if a disconnection of the inst from the netlist would cause  
power management inconsistency

PreservedUMPB Set if clock node is a User Module Port Bit which is preserved

Contact Cadence Support if any of the following reasons are listed:

ClockGatesAlways Set if inst is clock gate, considered always dont\_touch

ClockLogicAlways Set if inst is clock logic, considered always dont\_touch

ModelsRoot Set if the clock node is the clock root  
 NoRoot Set if the clock node has no root  
 RootIgnored Set if the clock root is ignored  
 SpineCell Set if cell is a clock spine inst and is marked as dont\_touch  
 The possible general reasons are:  
 DrivesAcrossPowerDomains The inst drives across power domain boundaries  
 NodeHasSGConstraints The inst has user mode skew group constraints in default mode  
 ClockDriverCannotCloneInverter  
 ClockDriverCreatedByBuffLongNets Set if the inst was created by 'Buffering long nets'.  
 ClockDriverInverterCloningDisabled The inst is an inverter and cloning inverters is disabled  
 UnclonableClockSource Set if the inst carries the -source of an SDC clock  
 UnclonableIODelayReference Set if the inst is associated with an I/O timing constraint  
 UnclonablePLLReference Set if the inst is associated with a PLL constraint  
 UnclonablePLLFeedback Set if the inst is analyzed as a PLL feedback  
 UnclonablePLLOutput Set if the inst is analyzed as a PLL output  
 UnsupportedNodeType Set if the inst is not a supported type. Supported types are: clock gate, clock logic and clock driver.  
 SingleOrZeroFanoutNode Set if the inst has fewer than two fanout.  
 Contact Cadence Support if any of the following reasons are listed:  
 NoCellInst  
 ClockLogicMultiOutputCell  
 IgnoredTree  
 IsUnclonable  
 DiscreteClockGate  
 NotTreeViewNode  
 OutputPinCellPinNull  
 ClockDriverNeedToKeep  
 Valid values: list string  
**Type:** string  
**Default:** ""  
**Edit:** Yes

#### cts\_cannot\_merge\_reasons

A list of reasons to explain why the inst could not be merged.  
 The attribute returns a list of reasons why the inst cannot be merged. These attributes are set on clock gates and clock logic instances.  
 For clock gates, the merge is driven by the enable function. If two clock gates share the same enable function, potentially they may be merged together. The reasons explains why potentially mergeable clock gates could not in fact be merged.  
 For clock logic, the merge is driven by the logical expression, or logic function, at the clock output pin. If two clock logic express the same logic function, at least potentially they may be merged. The reasons lists why the potential merge could not be realized.  
 User configuration disabled merging:

ClockGateMergingDisabledOnTree Merging disabled: attribute cts\_declone\_clock\_gates  
ClockLogicMergingDisabledOnTree Merging disabled: attribute cts\_declone\_clock\_logic  
IsDontTouch The instance cannot be merged as it is marked dont\_touch  
Attributes of a clock node rendered it unmergeable:  
GloballyUnique The clock node has no potential candidate with which it might merge  
UniqueUnderParent There are potential merge candidates, but not on the same clock net  
HasSkewGroupConstraints The instance carries a skew group source, sink or ignore pin  
UndrivenEnablePins The clock gate has a floating enable input  
UndrivenRetentionPins The clock gate has a floating retention input  
UndrivenTestPins The clock gate has a floating test enable input  
DifferentSplitOnInputs The multi-input clock logic has different skew groups at its clock in  
SiblingsNotMergeable Could not merge because all other candidates were unmergeable  
Otherwise mergeable clock nodes may have incompatibilities that prevent merging:  
DifferentSkewGroupForInputs Two clock nodes have different skew groups at their clock in  
DifferentSkewGroupForOutputs Two clock nodes have different skew groups at their clock  
DifferentCellFamilies Two clock nodes belong to incompatible cell families  
DifferentNumberOfInputPins Two clock nodes have different numbers of input pins  
DifferentNonStandardInputs Two clock gates have non-standard\* inputs which are non-ec  
MismatchingNonClockInputs Two clock nodes have non-clock inputs which receive non-equivalent signals  
MismatchingClockInputs Two clock nodes have clock inputs which receive non-equivalent  
MismatchingPowerDomains Two clock nodes are in incompatible power domains  
NotLogicalClones Two clock nodes have outputs which are not logically equivalent  
DifferentNumberOfParents Two clock nodes have different numbers of clock-carrying inputs  
DifferentOutputPowerContext Two clock nodes have outputs with different power domain/voltage  
DifferentInputPowerContext Two clock nodes have inputs with different power domain/voltage  
IncompatibleRestrictedRegions Two clock nodes have incompatible restricted regions  
DifferentAnnotations Two clock nodes have different annotations on its pins  
(\*) Non-standard inputs on a clock gate are inputs besides the clock, enable, test enable and retention inputs.  
Valid values: list string  
**Type:** string  
**Default:** ""  
**Edit:** Yes

## inst\_obs\_shape

### Parent Objects

## Definition

This corresponds to one of the .base\_cell.obs\_layer\_shapes.shapes (LEF OBS shapes) for a given inst. It carries a link to the 'inst' object, that a 'shape' object does not have. This allows GUI operations that need both the shape and the inst object together to select, highlight or query the shape. It can only be accessed by selecting the object with the GUI.

| Attribute        | Description                                                                                                                                                                                                                                                                |

## io\_constraint

### Parent Objects

[design](#), [root](#)

### Definition

IO object for block (term) or chip design (inst) constraints

| Attribute | Description |
|-----------|-------------|
|-----------|-------------|

|              |                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| area         |                                                                                                                                                                                  |
|              | <p>Area of the instance as defined by the LEF MACRO SIZE or OVERLAP information</p> <p><b>Type:</b> <a href="#">area</a></p> <p><b>Default:</b> ""</p> <p><b>Edit:</b> No</p>    |
| bbox         |                                                                                                                                                                                  |
|              | <p>Bounding box of the inst overlap rects. This is only correct if type = inst.</p> <p><b>Type:</b> <a href="#">rect</a></p> <p><b>Default:</b> ""</p> <p><b>Edit:</b> Yes</p>   |
| indent       |                                                                                                                                                                                  |
|              | <p>Indent of instance from the boundary of the design</p> <p><b>Type:</b> <a href="#">coord</a></p> <p><b>Default:</b> no_value</p> <p><b>Edit:</b> Yes</p>                      |
| inst         |                                                                                                                                                                                  |

## Definition

A layer from the LEF or OA technology file.

| Attribute          | Description                                                                                                                                                                                       |

|                | <p>An index into the routing layers. It is 1 for the first LEF TYPE ROUTING layer in the technology file, 2 for the second routing layer, etc. It is 0 for the layer just below the first routing layer (e.g a poly layer or non-routing metal layer that may have pin shapes in some cells). The route_index is -1 for any non-routing layers, or LEF routing layers with LEF TYPE MIMCAP or TYPE BACKSIDE. In OpenAccess, the routing layers are determined by the LEFDefaultRouteSpec validLayers list.</p> <p><b>Type:</b> int</p> <p><b>Default:</b> ""</p> <p><b>Edit:</b> No</p>                                                                                                                      |

|                   | <p>This is set by add_tracks or by reading an OA design with widthSpacingPatterns defined. It is a list of {width pitch repeat} values that created the tracks. For example, {1.5 2.5 1} {1.0 2.0 3} means a track of 1.5 width, 2.5 track-to-track pitch repeated 1 time, and then a track with width 1.0, track-to-track pitch 2.0 repeated 3 times, then the full pattern repeats. If this is not an SADP layer, there is no width assigned to the track, and a width value of 0.0 is returned. For a horizontal routing layer, the width and pitch are Y values.</p> <p><b>Type:</b> <a href="#">string*</a><br/> <b>Default:</b> ""<br/> <b>Edit:</b> No</p>      |

## library\_set

### Parent Objects

[timing\\_condition](#), [root](#)

### Definition

Specifies a group of library files to be treated as a single entity so that higher-level descriptions (delay\_corners) can simply refer to the library configuration by name. All non-physical libraries used by the timing must be part of a library\_set - including Liberty, AOCV, SOCV, and signal integrity library formats. Use the create\_library\_set command to define new library\_sets and the update\_library\_set command to update the attributes of existing library\_sets.

| Attribute     | Description                                                                                                                                                                          |

# marker

## Parent Objects

[design](#), [root](#)

## Definition

A violation marker. All markers have a .bbox and .originator set, and optionally .polygon for polygon shapes. Other attributes depend on the marker. Markers created by internal check or report commands will have .originator != external and have a .layer, .type, .subtype, .message, and .message\_id defined by those commands. Markers created with read\_markers or create\_marker will have .originator == external and will have .layer, .user\_type, .user\_subtype, .user\_originator, and .message based on the external input.

| Attribute | Description |
|-----------|-------------|
|-----------|-------------|

|            |                                                                                                                                                                                                        |

|                              | <p>Specifies the preferred extra spacing tracks for this net. It adds extra spacing in units of "routing tracks" (which vary in width on different layers). Use this attribute to give critical nets extra space to reduce coupling. Setting it to 1 gives the routing 1 extra routing pitch of spacing (e.g. one empty routing track on both sides of each wire). This parameter creates a soft rule and, if the design is congested, might not give the extra space to the net. If you specify this attribute, Early Global Route also gives additional space to the specified nets.</p> <p><b>Type:</b> <a href="#">int</a><br/> <b>Default:</b> 0<br/> <b>Edit:</b> Yes</p> |

|                           | <p>Specifies one or two PG nets to use as shields for critical nets. You should route these PG nets before routing this net so the shields can be connected to the PG mesh properly when the signal router runs. Normally only one shield net is used for shielding both sides. You can also specify two route_shield_nets (one for each side), but you cannot control which side is used if two nets are given. The shields are added as special_wires on each side of the signal wires with .shield_net pointing at the net that is shielded. The signal wires should be shielded for the full length, except near pins.</p> <p><b>Type:</b> obj(net)*<br/> <b>Default:</b> {}<br/> <b>Edit:</b> Yes</p> |

## opcond

### Parent Objects

[timing\\_condition](#), [root](#)

### Definition

An opcond represents a named operating condition which is defined by specific process, voltage, and temperature values. Opcond objects may preexist within a Liberty library or "virtual" opconds may be created using the create\_opcond command. Virtual opconds can also be modified by using the update\_opcond command.

|             | <p>The Liberty tree_type model. It is an enum with these choices: none means there is no tree_type value given; best_case_tree models each load pin is close to the driver, so wire capacitance is incurred, but wire resistance is ignored; balanced_tree models when all load pins are on equal branches, so each load pin has an equal portion of the total wire cap and resistance; worst_case_tree models when the load pin is at the extreme end of the wire, so each load pin incurs the full wire capacitance and resistance</p> <p><b>Type:</b> <a href="#">enum</a><br/> <b>Enum Values:</b> none best_case_tree balanced_tree worst_case_tree<br/> <b>Default:</b> ""<br/> <b>Edit:</b> No</p> |

Indicates how this pg\_base\_pin is used from the LEF USE value or OA equivalent. Only power or ground enum values make sense in normal usage, but if there are conflicts between Liberty and LEF/OA definitions, you may have pg\_base\_pins that are marked in LEF/OA with the other values.

**Type:** [enum](#)

**Enum Values:** signal analog power ground clock

**Default:** ""

**Edit:** No

|                         | <p>Specifies the maximum fanout value for each "steiner tree" for trunk routing (e.g. route_pattern = trunk). Normally, every pg_pin instantiated by the same pg_base_pin honors the same max fanout. So user only needs to set it on the pg_base_pin. For the few cases where pg_pin has different requirement than the pg_base_pin, NanoRoute will honor the one on pg_pin. This is intended for usage on always-on power pins routed by the signal router rather than the power router, It is most commonly used during late ECO routing to meet EM and IR limits by forcing an isolated pg_pin into its own "cluster" by setting the value to 1.</p> <p><b>Type:</b> <a href="#">int</a><br/> <b>Default:</b> 0<br/> <b>Edit:</b> Yes</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
