|                      | <p>By default this value is true, and most command -layer &lt;layer&gt; options require a LEF/OA layer name, or a routing-layer index value (e.g. 1 for the first routing layer, 2 for the second, etc.) as input. If this global is false, then an older style abbreviation is also allowed (e.g. M1 for the first routing layer, M2 for the second routing layer, etc.). This layer abbreviation style is not recommended, and is only allowed for backward compatibility to migrate older scripts. Eventually this global will be removed, so you should modify your scripts to use LEF/OA layer names, or routing-layer index values for -layer options to avoid problems in the future.</p> <p><b>Type:</b> <a href="#">bool</a><br/> <b>Default:</b> true<br/> <b>Edit:</b> Yes<br/> <b>Reference:</b> <a href="#">layer_name_no_abbreviation</a></p> |

| tcl_partial_cmd_argument_matching | <p>Use this switch to control command argument partial matching as well as enum value partial matching. When it's turned on, argument '-opt' will match '-option' if no other argument name begins with -opt. Default is 'quiet', which means to silently allow partial-matching when there is ambiguity. 'warn' means allow partial-matching with a warning message. 'error' means to disallow partial-matching, and error out.</p> <p><b>Type:</b> <a href="#">enum</a><br/> <b>Enum Values:</b> quiet warn error<br/> <b>Default:</b> quiet<br/> <b>Edit:</b> Yes<br/> <b>Reference:</b> <a href="#">tcl_partial_cmd_argument_matching</a></p> |

|         | <p>Specifies the minimum spacing allowed between the blockage and any other shape on the same layer (e.g. DEF BLOCKAGES with +SPACING). If there is no spacing value defined, the default is -1 in DB units, which will appear like a small value &lt; 0 (e.g.-0.0005 if the get_db db_units is 2000). The design_rule_width and spacing attributes are not allowed to have non-default values at the same time, so the spacing value cannot be changed when the design_rule_width attribute's value is also set. To reset the spacing value use [set_db -dbu route_blockages .spacing -1].</p> <p><b>Type:</b> <code>coord</code><br/> <b>Default:</b> <code>no_value</code><br/> <b>Edit:</b> Yes</p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|         | <p>The routing blockage type. default: means the blockage is completely blocked and check_drc will treat it like min-width routing for spacing checks. partial: means a percentage of the routing resource is available on the layer (see density attribute). fills: means do not add any metal fill in the area. except_fills: means do not add objects except metal fills in the area.slots: means don't add slots to the area. slots is not used in Innovus but is allowed to match DEF. The type corresponds to the DEF BLOCKAGES + FILLS or + SLOTS value. There is no DEF syntax for 'partial', so partial blockages are currently lost when written to DEF. core_eol is an end-of-line blockage added by finish_floorplan -add_core_end_of_line_blockage using LEF COREEOLBLOCKAGE statements. block_eol: An end-of-line blockage added by finish_floorplan - add_block_eol_blockage using LEF BLOCKEOLBLOCKAGE statements.</p> <p><b>Type:</b> <code>enum</code><br/> <b>Enum Values:</b> default slots fills except_fills partial core_eol block_eol boundary_eol<br/> <b>Default:</b> <code>""</code><br/> <b>Edit:</b> Yes</p> |

|                        | <p>The net should use a stacked via from output pins up to the given layer before starting normal routing. This is normally used to force the routing to higher layers with wider widths to reduce wiring resistance or avoid EM current limits for high-drive outputs. If output_stack_via_rule or input_stack_via_rule is also specified, the specified stack via rule is used for the input or output pins accordingly. If both output_stack_via_rule/input_stack_via_rule are not specified, a single-cut stacked-via will be used for the output pins only.</p> <p><b>Type:</b> obj(layer)<br/><b>Default:</b> ""<br/><b>Edit:</b> Yes</p> |

# sdp

## Parent Objects

inst, design, root

## Definition

A structured datapath object. Each sdp is formed hierarchically from a list of sdps below it. Each sdp can be a row, column, space or inst (see .type). At the leaf-level, an sdp can only be a space or inst. See the create\_sdp\_group command for more help.

| Attribute | Description                                                                                                                                                                                                                                                                        |

## shape

### Parent Objects

[route\\_blockage](#), [place\\_blockage](#), [layer\\_shape](#)

### Definition

A LEF PIN or OBS single-layer shape (RECT, POLYGON or PATH statement). Note that PATH statements are converted to one or more equivalent rect shapes. See shape\_vias for a LEF VIA used in a PIN or OBS statement.

| Attribute | Description                                                                                                                                                                                                       |

## special\_via

### Parent Objects

[net](#)

## Definition

A special\_via is normally used for power-vias, flip-chip routing, and sometimes pre-routed nets. special\_vias (along with special\_wires) are not changed during signal routing. They appear in the DEF SPECIALNETS section.

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                | <p>Is the mask number for the lower, left cut of the via. The mask for the other cuts of the special_via are derived from the via_def by "shifting" the via_def's cut masks to match. So, if the via_def lower, left cut is mask 1, and the special_via cut_mask is set to 3, then all the via_def cuts on mask 1 become mask 3 for this special_via, and similarly cuts on 2 shift to 1, and cuts on 3 shift to 2. See the layer .num_masks attribute for the max mask value allowed. See the DEF manual section on 'Multi-Mask Layers with Special Wiring' for figures and examples. A value of 0 indicates the cut layer is uncolored, or the layer is not a multi-mask layer.</p> <p><b>Type:</b> <a href="#">int</a><br/> <b>Default:</b> 0<br/> <b>Edit:</b> Yes</p> |

|                | <p>Is the mask number for the lower, left shape on the top layer of the via. Normally there is only one shape on the top layer of a via, but if there are two or more top layer shapes, then the mask for the other shapes on the top layer are derived from the corresponding via_def mask values by "shifting" the via_def's mask values to match. See the DEF manual section on 'Multi-Mask Layers with Special Wiring' for figures and examples. A value of 0 indicates the top layer is uncolored, or the layer is not a multi-mask layer.</p> <p><b>Type:</b> <a href="#">int</a></p> <p><b>Default:</b> 0</p> <p><b>Edit:</b> Yes</p> |

## Definition

The LEF or OA technology and library data used by a given design. It has all the layers, base\_cells, route\_rules, via\_defs, etc. for a given process technology node. It may be used by one or more design objects.

| Attribute | Description |

## timing\_condition

### Parent Objects

[delay\\_corner](#), [root](#)

### Definition

A timing\_condition represents a set of libraries at a specific operating condition - effectively defining a device corner. When assigned to a power domain - the domain uses the library and PVT bindings defined by the timing\_condition. Timing conditions may be assigned to one or several power domains in the design via the delay\_corner object's timing condition attributes. Use the create\_timing\_condition and update\_timing\_condition commands to create and modify timing\_conditions.

| Attribute    | Description                                                                                                                                                                                                         |

## trim\_grid

### Parent Objects

[design](#), [root](#)

### Definition

Trim grid pattern. Equivalent to LEF TRIMMETALTRACK statement that defines the grids that trim shapes must align to. See the LEF manual for more descriptions, figures and examples of how these attributes are defined.

| Attribute | Description                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bottom_mask |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | <p>Is the mask number for the lower, left shape on the bottom layer of the via. Normally there is only one shape on the bottom layer of a via, but if there are two or more bottom layer shapes, then the mask for the other shapes on the bottom layer are derived from the corresponding via_def mask values by "shifting" the via_def's mask values to match. See the DEF manual section on 'Multi-Mask Patterns for Routing Points' for figures and examples. A value of 0 indicates the bottom layer is uncolored, or the layer is not a multi-mask layer.</p> <p><b>Type:</b> <a href="#">int</a><br/> <b>Default:</b> 0<br/> <b>Edit:</b> Yes</p> |

|                   | <p>Is the mask number for the lower, left cut of the via. The mask for the other cuts of the via are derived from the via_def by "shifting" the via_def's cut masks to match. So, if the via_def lower, left cut is mask 1, and the via cut_mask is set to 3, then all the via_def cuts on mask 1 become mask 3 for this via, and similarly cuts on 2 shift to 1, and cuts on 3 shift to 2. See the layer .num_masks attribute for the max mask value allowed. See the DEF manual section on 'Multi-Mask Patterns for Routing Points' for figures and examples. A value of 0 indicates the cut layer is uncolored, or the layer is not a multi-mask layer.</p> <p><b>Type:</b> <a href="#">int</a><br/> <b>Default:</b> no_value<br/> <b>Edit:</b> Yes</p> |

## via\_def

### Parent Objects

[route\\_rule](#), [tech](#), [shape\\_via](#), [via](#), [special\\_via](#), [root](#)

### Definition

A via definition. This is equivalent to the LEF/DEF VIA section statements. A via\_def can be either a parameterized via (VIA with VIARULE parameters), or a fixed via (VIA with just RECT statements). See the LEF/DEF manual VIA section for more details.

| Attribute    | Description                                                                                                                                 |

|                | <p>Via resistance in ohms that is derived from LEF or OA data. This may not match the resistance of RC extraction results derived from extraction coefficient data. If the via is a fixed via with a resistance value defined in the LEF VIA definition statement or OA via_def, that value is returned. For vias without a resistance value, the resistance is computed from the cut-layer resistance_per_cut value and the number of cuts in the via (or equivalent cuts for a LEF CUTCLASS or OA cut_class via with different cut sizes). If both the via definition, and the cut-layer has no resistance value, then 0.0 is returned</p> <p><b>Type:</b> <a href="#">double</a></p> <p><b>Default:</b> ""</p> <p><b>Edit:</b> No</p> |

|                | The via_def_rule for this via_def. It is only set for generated vias created from via_def_rule parameters. See the LEF/DEF manual VIA statement with VIARULE for more details. It returns {} for fixed vias (e.g. a LEF/DEF VIA with only RECT values).<br><b>Type:</b> <a href="#">obj(via_def_rule)</a><br><b>Default:</b> ""<br><b>Edit:</b> No |

## via\_def\_rule

### Parent Objects

[via\\_def](#), [root](#)

### Definition

Equivalent of one LEF VIARULE GENERATE statement that has the rules to create new generated vias (e.g. LEF/DEF VIA statements with VIARULE parameters). See the LEF manual for more details.

| Attribute        | Description |
|------------------|-------------|
| bottom_enclosure |             |

# wire

## Parent Objects

net

## Definition

A 2-point wire segment intended for symbolic routing where the end-points normally align with other wire or via end-points, or end on a pin shape or special\_wire. The wire, via, and patch\_wire objects correspond to the DEF NETS symbolic routing data.

| Attribute       | Description                                                                                                                                                                           |
