The amount of insertion delay under this pin, broken down by the source of the pin insertion delay (PID).  
The value of this attribute is a Tcl dictionary of PID values, keyed on the source of that PID. This provides an 'exploded' view into the total pin insertion delay that is present, categorizing the various contributions by their origin.  
Valid Tcl dict keys:  
user Asserted by user Tcl scripting or restored from an older DB.  
sdc Extracted from SDC set\_clock\_latency by spec creation.  
sink\_type Asserted to reflect the impact of the cts\_sink\_type attribute.  
ilm Records the mean clock latency of the ILM clock network that is rooted at this pin.  
useful\_skew A useful skew generated by pre-CTS optimization.  
incremental An incremental offset, used to specify useful skews to incremental CTS.  
total The formal sum of the above contributions. This value is the 'overall' pin insertion delay accessible via the cts\_pin\_insertion\_delay attribute.  
Valid Tcl dict values: double | ignore | min | auto  
Reading the attribute returns a dict value that exposes the current state of the PID, recording all the PID sources and the associated PID value of each one. Sources whose value are auto are omitted. If there are no non-auto sources, the returned dict is empty. For convenience, the total is always included in the dict if it is non-auto.  
Writing a dict value to the attribute will update each of the specified sources with the specified PID value. The total PID value will then be updated. Sources in the dict that are assigned a value of 'auto' will be reset. Sources omitted from the dict are left unchanged from their current value: assigning an empty dict is a no-op.  
Resetting the attribute will clear all the sources and the total back, resetting them to the default value of 'auto', thereby completely removing the PID from the pin.  
Valid values: A Tcl dictionary of PID values, keyed on PID source.  
**Type:** [string](#)  
**Allowed -index values:** delay\_corner  
**Default:** ""  
**Edit:** Yes

cts\_pin\_route\_type\_propagation

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                                 | <p>Clock tree definition will, by default, not continue through certain types of cell arc (for instance, the clock to Q arc in a DFF). This attribute allows you to override this default behavior, permitting the clock tree to trace through such a cell.</p> <p>The attribute should be configured on the input pin at which the clock arrives. The value of the attribute specifies the output pin to which the clock should propagate. The specified output pin must be another pin on the same instance. The output pin may be specified either by its fully qualified name (i.e. inclusive of the instance name), or else simply by its local (cell-relative) name.</p> <p>There must be a pre-existing (library-defined) chain of one or more delay arcs that connect the input and output pins together. It is not possible to use trace_through_to to synthesize delay arcs.</p> <p>If multiple input pins are annotated on a given instance, the value of trace_through_to at each of those pins must select the same output pin: i.e. the configuration must identify a single clock output for the instance. If multiple clock outputs are required then trace_through_to should not be used: instead define a generated clock tree at each of the clock-carrying outputs.</p> <p>If the configuration of trace_through_to settings for a given instance does not meet these requirements, a warning will be issued and the settings for that instance will be ignored.</p> <p>Note: if both trace_through_to and library_trace_through_to are applicable at a given netlist instance pin, the trace_through_to value takes precedence.</p> <p>Valid values: pin</p> <p><b>Type:</b> string<br/><b>Default:</b> ""<br/><b>Edit:</b> Yes</p> |

|                          | <p>The same as .escaped_name without any \ escape chars. This name is commonly used to solve problems with \ escape chars in Tcl scripts unless you carefully use list operators. Like SDC commands, 'get_db insts i1/i2' will first try to match i1/i2, and if not found then match i1\i2 so flattening hierarchical names (e.g. with ungroup) does not require changing the names in Tcl scripts.</p> <p><b>Type:</b> string<br/><b>Default:</b> ""<br/><b>Edit:</b> No</p> |

|             | <p>The max placement density percent allowed inside this place_blockage. It must be in the range of 5 to 100, in steps of 5. It is only valid if the type = partial or soft. For example, a partial placement percentage of 75 percent means that up to 75 percent of placement density is allowed in the area. If the type is not partial or soft, a value of 0 is returned.</p> <p><b>Type:</b> double</p> <p><b>Default:</b> ""</p> <p><b>Edit:</b> Yes</p> |

|                                | <p>The amount of insertion delay under this pin, broken down by the source of the pin insertion delay (PID).</p> <p>The value of this attribute is a Tcl dictionary of PID values, keyed on the source of that PID. This provides an 'exploded' view into the total pin insertion delay that is present, categorizing the various contributions by their origin.</p> <p>Valid Tcl dict keys:</p> <ul style="list-style-type: none"> <li>user Asserted by user Tcl scripting or restored from an older DB.</li> <li>sdv Extracted from SDC set_clock_latency by spec creation.</li> <li>sink_type Asserted to reflect the impact of the cts_sink_type attribute.</li> <li>ilm Records the mean clock latency of the ILM clock network that is rooted at this pin.</li> <li>useful_skew A useful skew generated by pre-CTS optimization.</li> <li>incremental An incremental offset, used to specify useful skews to incremental CTS.</li> <li>total The formal sum of the above contributions. This value is the 'overall' pin insertion delay accessible via the cts_pin_insertion_delay attribute.</li> </ul> <p>Valid Tcl dict values: double   ignore   min   auto</p> <p>Reading the attribute returns a dict value that exposes the current state of the PID, recording all the PID sources and the associated PID value of each one. Sources whose value are auto are omitted. If there are no non-auto sources, the returned dict is empty. For convenience, the total is always included in the dict if it is non-auto.</p> <p>Writing a dict value to the attribute will update each of the specified sources with the specified PID value. The total PID value will then be updated. Sources in the dict that are assigned a value of 'auto' will be reset. Sources omitted from the dict are left unchanged from their current value: assigning an empty dict is a no-op.</p> <p>Resetting the attribute will clear all the sources and the total back, resetting them to the default value of 'auto', thereby completely removing the PID from the pin.</p> <p>Valid values: A Tcl dictionary of PID values, keyed on PID source.</p> <p><b>Type:</b> string</p> <p><b>Allowed -index values:</b> delay_corner</p> <p><b>Default:</b> ""</p> <p><b>Edit:</b> Yes</p> |

|                                 | <p>Clock tree definition will, by default, not continue through certain types of cell arc (for instance, the clock to Q arc in a DFF). This attribute allows you to override this default behavior, permitting the clock tree to trace through such a cell.</p> <p>The attribute should be configured on the input pin at which the clock arrives. The value of the attribute specifies the output pin to which the clock should propagate. The specified output pin must be another pin on the same instance. The output pin may be specified either by its fully qualified name (i.e. inclusive of the instance name), or else simply by its local (cell-relative) name.</p> <p>There must be a pre-existing (library-defined) chain of one or more delay arcs that connect the input and output pins together. It is not possible to use trace_through_to to synthesize delay arcs.</p> <p>If multiple input pins are annotated on a given instance, the value of trace_through_to at each of those pins must select the same output pin: i.e. the configuration must identify a single clock output for the instance. If multiple clock outputs are required then trace_through_to should not be used: instead define a generated clock tree at each of the clock-carrying outputs.</p> <p>If the configuration of trace_through_to settings for a given instance does not meet these requirements, a warning will be issued and the settings for that instance will be ignored.</p> <p>Note: if both trace_through_to and library_trace_through_to are applicable at a given netlist instance pin, the trace_through_to value takes precedence.</p> <p>Valid values: pin</p> <p><b>Type:</b> <a href="#">string</a><br/> <b>Default:</b> ""<br/> <b>Edit:</b> Yes</p> |

|                          | <p>The same as .escaped_name without any \ escape chars. This name is commonly used to solve problems with \ escape chars in Tcl scripts unless you carefully use list operators. Like SDC commands, 'get_db insts i1/i2' will first try to match i1/i2, and if not found then match i1\i2 so flattening hierarchical names (e.g. with ungroup) does not require changing the names in Tcl scripts.</p> <p><b>Type:</b> string<br/><b>Default:</b> ""<br/><b>Edit:</b> No</p> |

|                         | <p>Indicates how this port is used from the DEF PIN +USE value or OA equivalent. The legal values are: analog clock ground power signal. Note that timing analysis does not use these values; the .lib data instead (e.g. is_clock, is_analog, etc.). So the signal, clock or analog values are normally used by applications. The power/ground values are used by many applications. DEF +USE RESET, SCAN or TIEOFF are not supported, so read_def will ignore them, and keep existing DB use value.</p> <p><b>Type:</b> <a href="#">enum</a></p> <p><b>Enum Values:</b> signal clock power ground analog</p> <p><b>Default:</b> ""</p> <p><b>Edit:</b> Yes</p> |

## port\_shape

### Parent Objects

[design](#), [net](#), [root](#)

## Definition

This corresponds to one of a port's .physical\_pins.layer\_shapes.shapes, but is directly accessible from the design and root objects. It carries a link to the port object, that a layer\_shape object does not have. This allows GUI operations that need both the layer\_shape and the port object together as one object like delete\_obj or wire-editing commands.

| Attribute | Description                                                                                                                                                                                                                   |

## rc\_corner

### Parent Objects

[delay\\_corner](#), [root](#)

### Definition

The rc\_corner object represents a specific interconnect parasitic corner. It contains configuration information for controlling the extraction of the parasitics and possible scaling. Parasitic files are annotated or exported with respect to an rc\_corner object name. The rc\_corner object is typically referenced from one or many higher-level delay\_corner objects. Use the create\_rc\_corner command to define new rc\_corners and the update\_rc\_corner command to update the attributes of existing rc\_corners.

| Attribute      | Description                                                                                                                                                                                                                                                             |

## resistor

### Parent Objects

## Definition

After loading a Voltus IR-drop analysis result, you can select a resistor in the GUI. The pointer of the object is the same as its name, like resistor

| Attribute            | Description                                                                                                                                                                                                                                                                                                              |

|                                                       | <p>CCOpt attempts to keep the insertion delays of each clock tree a fixed multiple of the longest insertion delay that would result from a global skew approach. This multiple can be modified by design timing and the presence of other clock trees, but will start at a fixed fraction above the global skew insertion delay. This attribute specifies that fixed fraction.</p> <p>Valid values: real</p> <p>See also:</p> <p>.ccopt_auto_limit_insertion_delay_factor_skew_group</p> <p><b>Type:</b> <a href="#">double</a></p> <p><b>Default:</b> 1.5</p> <p><b>Edit:</b> Yes</p> <p><b>Reference:</b> <a href="#">ccopt_auto_limit_insertion_delay_factor</a></p> |

Specifies the clock halo in the x direction.  
Any x direction clock halo defined by this attribute is proportional to the cell width.  
The constant of proportionality is defined by the attribute value. For example:  
. If `cts_cell_density` = 0.25 then the x direction clock halo equals 3 \* cell width.  
. If `cts_cell_density` = 0.5 then the x direction clock halo equals cell width.  
. If `cts_cell_density` = 0.75 then the x direction clock halo equals cell width / 3.  
. If `cts_cell_density` = 1 then the x direction clock halo equals zero.  
This attribute can specify the x direction clock halo for all clock trees via:  
`set_db cts_cell_density 0.8`  
This attribute can specify the x direction clock halo per-clock tree via:  
`set_db clock_tree:<clk> .cts_cell_density 0.9`  
The following attributes can be used to assign x direction clock halos within CCOpt:  
`cts_cell_halo_x`  
`cts_cell_density`  
`cts_cell_halo_sites`  
Only one of these attributes is used to determine the clock halo in the x direction. The following rules determine which:  
. If `cts_cell_halo_x` is set to a non-auto value, then this defines the x direction clock halo. The attributes `cts_cell_density` and `cts_cell_halo_sites` have no effect.  
. If `cts_cell_halo_x` is set to auto and `cts_cell_density` is set to a non-auto value then `cts_cell_density` defines the clock halo in the x direction. The attribute `cts_cell_halo_sites` has no effect.  
. If both `cts_cell_halo_x` and `cts_cell_density` are set to auto then `cts_cell_halo_sites` defines the clock halo in the x direction.  
Valid values: 0.01 to 1  
See also:  
. `cts_cell_halo_x`  
. `cts_cell_halo_sites`  
**Type:** [string](#)  
**Default:** 0.75  
**Edit:** Yes  
**Reference:** [cts\\_cell\\_density](#)

`cts_cell_halo_mode`

Specifies how clock halos are used to determine the minimum legal separation between a clock instances. There are two possible modes 'max' and 'sum'. When set to 'max' the minimum legal separation is the larger of the two clock halos. When set to 'sum' the minimum legal separation is the sum of the two clock halos.

Valid values: max sum

---

cts\_cell\_halo\_rows

---

Specifies the clock halo in the y direction in rows for all clock cells.  
The following attributes can be used to assign y direction clock halos within CCOpt:  
cts\_cell\_halo\_y  
cts\_adjacent\_rows\_legal  
cts\_cell\_halo\_rows  
Only one of these attributes is used to determine the clock halo in the y direction. The following rules determine which:  
    . If cts\_cell\_halo\_y is set to a non-auto value, then this defines the y direction clock halo. The attributes cts\_adjacent\_rows\_legal and cts\_cell\_halo\_rows have no effect.  
    . If cts\_cell\_halo\_y is set to auto and cts\_adjacent\_rows\_legal is set to a non-auto value then cts\_adjacent\_rows\_legal defines the clock halo in the y direction. The attribute cts\_cell\_halo\_rows has no effect.  
    . If both cts\_cell\_halo\_y and cts\_adjacent\_rows\_legal are set to auto then cts\_cell\_halo\_rows defines the clock halo in the y direction.

**Type:** [int](#)  
**Default:** 1  
**Edit:** Yes  
**Reference:** [cts\\_cell\\_halo\\_rows](#)

cts\_cell\_halo\_sites

Specifies the clock halo in the x direction in sites for all clock cells.  
The following attributes can be used to assign x direction clock halos within CCOpt:  
cts\_cell\_halo\_x  
cts\_cell\_density  
cts\_cell\_halo\_sites  
Only one of these attributes is used to determine the clock halo in the x direction. The following rules determine which:  
. If cts\_cell\_halo\_x is set to a non-auto value, then this defines the x direction clock halo. The attributes cts\_cell\_density and cts\_cell\_halo\_sites have no effect.  
. If cts\_cell\_halo\_x is set to auto and cts\_cell\_density is set to a non-auto value then cts\_cell\_density defines the clock halo in the x direction. The attribute cts\_cell\_halo\_sites has no effect.  
. If both cts\_cell\_halo\_x and cts\_cell\_density are set to auto then cts\_cell\_halo\_sites defines the clock halo in the x direction.

|                                            | <p>If this attribute is set, the CTS algorithm will move logic that appears in the clock tree. "Logic" does not include clock gates, buffers, and inverters in a clock tree, which are always moved unless they are locked, or clock generators that are above the root of the clock tree. Usually, this will affect multiplexers used for selecting one of a number of clocks, or for switching between a test clock and the main clock. Setting this attribute may cause the clock tree to have a lower insertion delay, but might break datapath timing. During optimization, this is not a problem, because the timing will be automatically recovered during the optimization process.</p> <p>Valid values: true false</p> <p><b>Type:</b> <a href="#">bool</a><br/> <b>Default:</b> true<br/> <b>Edit:</b> Yes<br/> <b>Reference:</b> <a href="#">cts_move_logic</a></p> |

|                                        | <p>Specifies the route type. Setting this attribute binds an existing user-defined route_type to one or more types of clock tree nets. Binding a route_type to a type of clock tree nets means that all nets of that type (including the nets created by CTS) will be routed according to the specification of that route_type.</p> <p>In the most common usage, the route_type is bound to one of the three types of clock tree nets (top, trunk, or leaf) with the optional -net_type argument. Omitting the -net_type argument causes the route_type to be bound to all three types of clock tree nets. The optional -clock_tree &lt;pattern&gt; argument limits the binding to the clock trees whose name matches &lt;pattern&gt;. Omitting the -clock_tree argument causes the binding to apply to all clock trees.</p> <p>For a route_type to be used in CTS, it must be bound to at least one net type. If net_type is bound to any route_type, a default route_type will be created for that net type at the start of the CTS run.</p> <p>Valid values: names of route_types created with create_route_type</p> <p><b>Type:</b> <a href="#">string</a></p> <p><b>Default:</b> default</p> <p><b>Edit:</b> Yes</p> <p><b>Reference:</b> <a href="#">cts_route_type_leaf</a></p> |

|                        | <p>When set to true (the default), the CTS algorithm sizes logic that appears in<br/> the clock tree. "Logic" does not include clock gates, buffers, and inverters<br/> in a clock tree, which are always sized unless they are locked, or clock<br/> generators that are above the root of the clock tree. Usually, this affects<br/> multiplexers used for selecting one of a number of clocks, or for switching<br/> between a test clock and the main clock. Setting this attribute may cause the<br/> clock tree to have a lower insertion delay, but might change the cell types of<br/> logic gates in the clock tree, which in turn may require them to be moved<br/> slightly to find a legal location for the new cell.</p> <p>Valid values: true false</p> <p><b>Type:</b> <a href="#">bool</a><br/> <b>Default:</b> true<br/> <b>Edit:</b> Yes<br/> <b>Reference:</b> <a href="#">cts_size_logic</a></p> |

#### cts\_skew\_group\_report\_columns

A Tcl list of columns to include in skew group reports produced by the skew group report. You can use this attribute to specify the columns you would like to include in the skew group report, and the order in which the columns should appear.

Valid values:

capacitance  
distance  
event  
fanout  
increment  
lib\_cell  
location  
name  
slew  
status  
time

**Type:** [string](#)

**Default:** name lib\_cell event increment time slew capacitance location distance fanout status voltage

**Edit:** Yes

**Reference:** [cts\\_skew\\_group\\_report\\_columns](#)

#### cts\_skew\_group\_report\_histogram\_bin\_size

When set to a numeric value, that numeric value will be used as the histogram range size (in library units). For example, if the library time units are set to 1 nanosecond, a value of 0.010 for `report_skew_groups_histogram_bin_size` will result in histogram ranges of 10 picoseconds.

When set to auto, the size of the histogram ranges are dependent on the skew targets that are set. If a skew target is set for a given half corner and skew group combination, then the histogram range size will be 10% of the skew target for that half corner and skew target combination. If no skew target is set for a half corner and skew group combination but a skew target is set for the primary half corner and skew group combination, then the histogram range size will be 10% of the skew target for the primary half corner and skew group combination.

In the event that no skew targets are set and `report_skew_groups_histogram_bin_size` is set to auto, a default value of 10 picoseconds will be used for the histogram range size.

Valid values: auto | string

**Type:** [string](#)

**Default:** auto

**Edit:** Yes

**Reference:** [cts\\_skew\\_group\\_report\\_histogram\\_bin\\_size](#)

---

`cts_spec_config_base_pin_trace_through_to`

---

Clock tree definition will, by default, not continue through certain types of cell arc (for instance, the clock to Q arc in a DFF). This attribute allows you to override this default behavior, permitting the clock tree to trace through all instances of such a cell.

This attribute serves the same function as `trace_through_to`, except that here the clock path is specified at the level of the library cell.

The attribute should be configured on the input library pin at which the clock will arrive. The value of the attribute specifies the output library pin to which the clock should propagate. The specified output pin must be another pin on the same library cell. The output pin may be specified either by its fully qualified name (i.e. inclusive of the cell name), or else simply by its local (cell-relative) name.

There must be a pre-existing (library-defined) chain of one or more delay arcs that connect the input and output pins together. It is not possible to use `library_trace_through_to` to synthesize delay arcs.

If multiple input pins are annotated on a given library cell, the value of `library_trace_through_to` at each of those pins must select the same output pin: i.e. the configuration must identify a single clock output for the cell. If multiple clock outputs are necessary then `library_trace_through_to` should not be used: instead for each instance of the library cell, define a generated clock tree at each of the clock-carrying outputs.

If the configuration of `library_trace_through_to` settings for a given library cell does not meet these requirements, a warning will be issued and the settings for that cell will be ignored.

All instances of the library cell will be affected by this setting. If both `trace_through_to` and `library_trace_through_to` are applicable at a given instance pin, the `trace_through_to` value will take precedence.

Valid values: `base_pin`

**Type:** [string](#)  
**Default:** ""  
**Edit:** Yes

|                                                                   | <p>Controls whether spec creation will synthesize reporting-only skew groups. A reporting-only skew group is a skew group whose cts_skew_group_constrains attribute is 'none'. Such a skew group imposes no clock balancing constraint and will not be considered by CTS. The typical example is a generated clock that is synchronous to its master clock. The relationship between the two clocks implies that the sinks of both clocks should be balanced together. To model this, a clock spec created for such a design will have the skew group corresponding to the master clock span the domain of both the master clock and also the generated clock. The skew group of the generated clock is then a subset of the master clock skew group: as such it is a redundant constraint, and may be safely omitted. If synthesized, such a skew group will be created as a reporting-only skew group. When this attribute is set to false, reporting-only skew groups are completely omitted from the generated spec. When set to true, reporting-only skew groups are included in the generated spec, but are marked with the cts_skew_group_constrains attribute set to 'none'. Either way, they impose no balancing constraint.</p> <p>Valid values: true false</p> <p><b>Type:</b> <a href="#">bool</a><br/> <b>Default:</b> true<br/> <b>Edit:</b> Yes<br/> <b>Reference:</b> <a href="#">cts_spec_config_create_reporting_only_skew_groups</a></p> |

This attribute controls whether and how `create_clock_tree_spec` will extract through cells that have multiple outputs but where only one of those outputs has a clock emanating from it; call these types of instance multi-output single-clock instances.

If the feature is disabled, spec creation will not trace through multi-output single-clock instances. The resulting clock spec will specify a generated clock tree on the clock-carrying outputs of every multi-output instance. Clock-carrying inputs that are connected to each clock output by way of timing arcs will be generator inputs to the corresponding generated clock tree. The presence of these generated clock trees may impact CTS operations on the instance such as sizing, moving, and cloning.

If the feature is enabled, the resulting clock spec will include `cts_spec_config_trace_through` settings for multi-output single-clock instances. These settings will allow the instance to be treated as a clock instance, most commonly as a clock logic. In this case there will be no need for the generated clock tree on the clock-carrying output. The treatment of instances with multiple clock-carrying outputs is unchanged: on such an instance each clock-carrying output will take a generated clock tree, as before.

The feature may be enabled conditionally, such that it is only applied to multi-output single-clock instances which are combinational. In this case multi-output single-clock instances which are sequential will continue to take a generated clock tree on the clock output.

The possible values for this attribute are as follows:

- false - The feature is completely disabled.
- true - The feature is enabled for all cell types; both combinational and sequential.
- combinational - The feature is enabled for combinational cells, but disabled for sequential.

Valid values: false true combinational

**Type:** [string](#)  
**Default:** combinational  
**Edit:** Yes

|                                  | <p>The target maximum capacitive load to allow during clock tree synthesis. This attribute specifies a maximum (combined pin and wire) capacitance that the clock tree synthesis algorithm will allow any given base_pin to drive in a given clock tree when driving a given net_type. It is specified in library units. It currently only constrains the primary delay corner capacitance values - other delay corners can be specified but will not be constrained. This attribute is applied in addition to the max_capacitance constraints read from the liberty library data - the tightest (lowest) of the constraint specified by this attribute and the constraint present in the liberty data will be used. It also does not apply at the root pins of clock trees - to constrain those nets the cts_clock_tree_source_max_capacitance CCOpt attribute should be used instead. Valid values: auto   double</p> <p><b>Type:</b> <a href="#">string</a><br/> <b>Allowed -index values:</b> delay_corner<br/> <b>Default:</b> auto<br/> <b>Edit:</b> Yes<br/> <b>Reference:</b> <a href="#">cts_target_max_capacitance_trunk</a></p> |

This attribute has no effect if `cts_timing_connectivity_based_skew_groups` is set to 'off'.  
With timing connectivity based skew groups enabled, this attribute controls how CCOpt will address the synchrony of disjoint (i.e. non-overlapping) master (i.e. non-generated) SDC clocks.  
When this attribute is set to false, all disjoint master clocks are assumed to be mutually asynchronous. The skew groups generated by `create_clock_tree_spec` will not constrain the sinks of two such clocks to be balanced together.  
When this attribute is set to true, the synchrony of disjoint master clocks is determined by consulting the SDC assertions in accordance with the value of attribute `cts_timing_connectivity_based_skew_groups`.  
Additional skew groups will be generated by `create_clock_tree_spec`, such that the sinks of each pair of synchronous disjoint master clocks will be balanced together by CTS.  
Valid values true false  
**Type:** `bool`  
**Default:** false  
**Edit:** Yes  
**Reference:** `cts_timing_connectivity_based_skew_groups_balance_master_clocks`

`cts_timing_connectivity_info`

This attribute is populated by clock spec creation when timing connectivity based skew groups are enabled. Configuration of this attribute will be written to the generated spec. It documents the clock/clock balancing relationships that were determined for the production of timing connectivity based skew groups. This attribute is documenting only.

If timing connectivity based skew groups are not enabled, this attribute is not populated by spec creation.

The value of the attribute is a set of nested Tcl dictionaries, four levels in total. The top-level dictionary indicates the information category. Currently there is only one such category: 'clock\_relationships'. The second level is keyed on constrained mode name; the lowest level dictionaries are both keyed on SDC clock name. These keys taken together identify two SDC clocks in a given constraint mode. The leaf value specifies the resolved balancing relationships between the two SDC clocks. It an enum with the following members:

- direct - The two clocks are determined to belong to the same clock group and must be balanced together.
- indirect - The two clocks do not belong to the same clock group; however by transitive closure they must balance together.

Clocks in a direct or indirect balancing relationship will share one or more skew groups so as to ensure that their sinks are balanced together by CTS. Missing entries should be taken as 'need not balance'; i.e. the pair of SDC clocks have neither a direct nor indirect balancing relationship.

The indirect balancing relationship can be explored in more detail using this same Tcl dictionary to probe out the transitive closure over the direct balancing relationships that link two indirect balance clocks together. For example if clock A directly balances with clock B only, and clock B directly balances with clock C only; then clock A indirectly balances with clock C. Below is an example dict value, corresponding to clock groups {clkA clkB} {clkB clkC} in constraint mode cm1, and clock groups {clkP clkQ} {clkR clkS} in constraint mode cm2.

```
{clock_relationships {cm1 {clkA {clkB direct clkC indirect} clkB {clkA direct clkC direct} clkC indirect clkB direct}} cm2 {clkP {clkQ direct} clkQ {clkP direct} clkR {clkS direct} clkS {clkR di
```

Notice that although they are in separate clock groups, clkA and clkC nevertheless indirectly balance. This is due to fact that clkB is present in both clock groups. Note also that we omit information about the relationship between clkP and clkS: they are 'need not balance'.

**Type:** [string](#)  
**Default:** ""  
**Edit:** Yes

#### edit\_wire\_via\_type

Specifies the type of creating via.  
**Type:** [enum](#)  
**Enum Values:** auto regular special  
**Default:** auto  
**Edit:** Yes  
**Reference:** [edit\\_wire\\_via\\_type](#)

#### edit\_wire\_width

Specifies the width of patch wires.  
**Type:** [double](#)  
**Default:** 0.0  
**Edit:** Yes  
**Reference:** [edit\\_wire\\_width](#)

#### edit\_wire\_width\_horizontal

Specifies the width for horizontal wires.  
**Type:** [double](#)  
**Default:** 0.0  
**Edit:** Yes  
**Reference:** [edit\\_wire\\_width\\_horizontal](#)

#### edit\_wire\_width\_vertical

Specifies the width of vertical wires.  
**Type:** [double](#)  
**Default:** 0.0  
**Edit:** Yes  
**Reference:** [edit\\_wire\\_width\\_vertical](#)

#### edit\_wire\_wire\_override\_spec

Contains the details of the override specification.  
**Type:** [string](#)  
**Default:** ""  
**Edit:** Yes  
**Reference:** [edit\\_wire\\_wire\\_override\\_spec](#)
