|              | <p>Specifies to adjust the trigger time of the current waveforms for the various functional modes (read/write/idle) of the custom macros. This parameter allows you to start the waveform before the trigger time (negative time support) to account for the setup time for the operation, as shown below:</p>  <p>The specified time will be applied to the computed trigger time for each mode in the trigger files generated by power analysis. For example, if the trigger time (from timing window/vector) is computed as 1ns, 2ns, and 3ns, and if you specify <code>set_power -trigger_time_adjustment -100ps</code>, the software will adjust the trigger time to .9ns, 1.9ns, and 2.9ns.</p> |
| <i>value</i> | <p>Specifies power in milliwatts during static power calculation or piecewise linear (<code>-pwl</code>) current waveform, during dynamic power calculation for cell or instance. The command accepts a unit specification (e.g. 10w).</p> <p>The format of the PWL waveform is:<br/> <code>{time1 current1 time2 current2 ...time_n current_n}</code></p> <p>Time is in ns and current in mA.</p> <p><b>Example:</b><br/> <code>set_power -pwl_waveform -pg_net {} -cells BUFX2MTL {0 0 10 0 10.1 5 10.5 0}</code></p> <p>Here, at 0ns its value is 0mA, at 10ns its value is 0mA, at 10.1ns its value is 5mA, and so on.</p>                                                                                                                                                          |

## Examples

- The following command sets power for vdd rail to 10 milliwatts:  
`set_power -pg_net vdd 10mw`
- The following command sets a power value of .005 milliwatts on power net vdd for instance `clkin_neg_L14_I1`:

```
set_power -pg_net vdd -insts Top/A/clkin_neg_L14_I1 .005
```

- The following command sets a power value of .005 milliwatts for any cell named INVX2 in the design:

```
set_power -cells INVX2 .005mw
```

- The following command defines a piecewise linear waveform of {0 0 10 0 10.1 5 10.5 0} for the cell of type BUFX2MTL for all power rails.

```
set_power -pwl_waveform -pg_net {} -cells BUFX2MTL {0 0 10 0 10.1 5 10.5 0}
```

- The following command specifies the leakage power for the cell DFFRX1.

```
set_power -leakage -cells DFFRX1 10mw
```

- The following commands specify the target leakage power for power nets VDD1 and VDD2.

```
set_power -leakage -pg_net VDD1 100mw
```

```
set_power -leakage -pg_net VDD2 200mw
```

- The following command specifies the PWL description of current for the instance SEHD130\_1024X32X1CM8. The -sticky option tells the software to use the specified PWL simulation based waveforms as is.

```
set_power -pwl_waveform -insts SEHD130_1024X32X1CM8 -sticky {0 0 1 1 2 2 7 0}
```

- The following command scales the total power of the instance i\_1 by a scale factor of 2:

```
set_power -scale_factor 2 -insts i_1
```

- The following command sets the total power of the design to 20mw while keeping the clock network power the same:

```
set_power 20mw -exclude_clocks {all}
```

- The following command assigns a switching power of 3mw to all instances of the cell AND1:

```
set_power -cells AND1 -switching 3mw
```

- The following command assigns 2mw power to all cells that match the specified pattern:

```
set_power -cells[get_lib_cells NAND*] 2mw
```

- The following command specifies that mode1 switches in the first cycle, mode2 switches in the third cycle and no switching in others:

```
set_power -dynamic_switch_pattern { mode1 0 mode2 0 }
```

- The following command resets power of all cells that match the specified pattern:

```
set_power -reset -cells[get_cells A/*]
```

- The following command does not schedule DDV mode scan\*:

```
set_power -base_cells { * } -exclude_ddv_modes { scan* }
```

- The following command does not schedule DDV mode scan\* for instance "A1":

```
set_power -insts { A1 } -exclude_ddv_modes { scan* }
```

- The following command only schedules DDV mode names with the `*read*` and `*write*` pattern:

```
set_power -base_cells { * } -include_ddv_modes { *read*, *write* }
```

- The following commands specify the toggle time for the pin names Q7 and Q6:

```
set_power -dynamic_switch_event { 1.1ns r 5.5ns f } -insts clk_b_i2 -pin Q7
```

```
set_power -dynamic_switch_event { 2.2ns r 6.6ns f } -insts clk_b_i2 -pin Q6
```

## Trigger File Format

For specifying a custom trigger file, you must use the `-custom_macro_pwl_waveform` parameter. The format of the trigger file is:

| Trigger File Format                                                                   | Description                                                                                                                                                                  |
|---------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>#Cell names</b>                                                                    |                                                                                                                                                                              |

## Example of a Custom Macro Power Trigger File

```
MASTER_CELL SRAM_A1
```

```
COMPANION_CELLS { SRAM_A2, SRAM_A3, SRAM_A4, SRAM_A5 }
 MODE_NAME WRITE
 CONDITIONAL_INPUT = (!SD & !SLP & !CEB & !WEB)
 CONDITIONAL_PIN = CLK { RISE }
 USER_PWL_FILE write_rise.txt
 END_MODE
 MODE_NAME READ
 CONDITIONAL_INPUT = (!SD & !SLP & !CEB & WEB)
 CONDITIONAL_PIN = CLK { RISE }
 USER_PWL_FILE read_rise.txt
 END_MODE
 ...
END
```

### Example of “USER\_PWL\_FILE” (Multiple regions)

```
UNIT CURRENT mA
UNIT TIME ns

```

# set\_power\_analysis\_temperature

```
set_power_analysis_temperature value
[-help]
```

Sets the temperature for static power calculation.

In the presence of a trilib set, the internal and leakage power will be interpolated as the per the given temperature specification.

## Parameters

|       |                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                |
| value | <p>Specifies the temperature for static power calculation.</p> <p><b>Note:</b> The static power calculation software gets the temperature value of each instance from the following sources (in order of precedence):</p> <ul style="list-style-type: none"><li>• Instance temperature file</li><li>• set_power_analysis_temperature command</li><li>• The current operating condition temperature</li></ul> |

## set\_power\_include\_file

```
set_power_include_file
file
[-block string]
[-reset]
```

Specifies a power analysis include file. You can use the `set_power_include_file` command to specify certain commands of the dynamic engine which do not have a Voltus equivalent. For more information on these commands, refer to the Power Analysis Options chapter.

The `set_power_include_file` command is required only if the `power_static_netlist` attribute is set to `def`.

**Note:** The `set_power_include_file` command is used to pass the legacy power analysis commands and `report_power` command options only in the dynamic mode (vectorbased and vectorless). If the `power_method` attribute is set to `static`, the `set_power_include_file` command is ignored.

### Parameters

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>          | Name of the include file. This file will include all commands that can not be translated to Voltus commands. In addition, you can also include the <code>report_power</code> command options to generate different power reports.                                                                                                                                                                                                 |
| <code>-block string</code> | Specifies the master cell name to which the powermeter options are to be applied. The parameter allows you to apply certain commands of the dynamic engine only to a specific block partition. This parameter allows you to apply the include options to a specific block instead of applying them globally to all blocks.<br><br>The <code>-block</code> parameter is applicable only to the block-based distributed power flow. |
| <code>-reset</code>        | Resets all options back to default values.                                                                                                                                                                                                                                                                                                                                                                                        |

### Examples

- The following command specifies a power include file of `power.inc`:  

```
set_power_include_file power.inc
```
- The following example shows the contents of the `power.inc` file.  
# power.inc file must use the pre-defined design and power objects as "design" # and "ChipPwr" respectively. The power output object is not supported.  

```
design calCellsToIgnore BUFX1
```

```
ChipPwr calRailVoltage VDD 1.2
```

```
report_power -net -out_file Net.rep
```

```
report_power -cell {INV*} -out_file Invpower.rep
```

# set\_power\_output\_dir

```
set_power_output_dir dir
[-reset]
```

Specifies the name of the directory that power information will be output to.

## Parameters

|            |                                                                                            |
|------------|--------------------------------------------------------------------------------------------|
| <i>dir</i> | Specifies the name of the directory in which power analysis output information is written. |
| -<br>reset | Resets all options back to default values.                                                 |

## Examples

- The following command specifies the output directory called `static_power_AvallOn` in which the power information is written.

```
set_power_output_dir static_power_AVallOn
```

# set\_switching\_activity

```
set_switching_activity
[-reset]
[-activity factor | -transition_density transition_density]
[-bidir_port]
[-clock clock_name]
[-duty value]
[-inst instance_name]
[-net net_name | -port port_name | -pin pin_name | -input_port port_name | -output_port
port_name]
[-period value]
[-integrated_clock_gate_ratio num]
[-combinational_clock_gate_ratio num]
[-hierarchy hierarchy_name]
[-scale value]
[-cell cell_name]
[-force]
[-unclocked]
[-quiet]
```

Specifies activity for nets, pins, and ports. This command is used to specify user-defined activities at specific pins/nets/ports. You must specify this command before `report_power`.

The `set_switching_activity` command can accept a net/pin/port list using the `get_pins/get_ports/get_nets` commands. You can use the `get*` commands to create a collection of nets/pins/ports whose name matches the supplied pattern list. Therefore, providing you with the flexibility in providing lists through use of regular filter patterns. This feature is supported in both static and dynamic analysis engines.

## Parameters

|                  |                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -activity factor |                                                                                                                                                                                                                                                                                                                                                                                                  |
|                  | Specifies the activity for a net, pin, or top-level port. The <i>activity_factor</i> specifies the number of times the net, pin, or port switches in a clock cycle. Enter any positive number. If if the activity is set to 0.5, the activity happens once for every two clock cycles. If the activity is set to 2.0, the activity happens two times per clock cycle. There is no default value. |
| -bidir_port      |                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-port port_name</code> |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                              | Specifies the name of a top-level port. The port names are in the following format: <i>top-level-port</i> . This parameter supports wildcards (*)                                                                                                                                                                                                                                                                                                  |
| <code>-unclocked</code>      | Applies activity (with reference period ) to all nets that doesn't have clock domain.                                                                                                                                                                                                                                                                                                                                                              |
| <code>-quiet</code>          | Suppresses all error and warning messages generated when the <code>set_switching_activity</code> command is run.                                                                                                                                                                                                                                                                                                                                   |
| <code>-reset</code>          | <p>Resets all specified options back to default values. The reset option should be the first option specified, otherwise all options set prior to this will be reset.</p> <p><b>Note:</b> You can selectively reset the pin/port/net specifications. In addition, you can also selectively reset the pin/port/net specifications of a list of objects through the <code>get_pins/get_ports/get_nets</code> commands.</p>                           |
| <code>-scale value</code>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                              | <p>Specifies to scale frequencies of the specified clock domains. This parameter allows you to scale transition densities of all instances associated with the clock domain by the specified scale factor to compute internal and switching power.</p> <p>This parameter must be specified with the <code>-clock</code> parameter. The <code>-scale</code> parameter is only applicable to static power and dynamic vectorless power analysis.</p> |

## Activity Precedence

See "[Activity Precedence](#)".

## Examples

- The following command specifies that net `n189` will switch once every ten clock cycles, with a clock period of `7520ns` and a duty cycle of 50 percent:

```
set_switching_activity -net n189 -activity 0.10 -period 7520ns -duty .5
```

- The following command sets the transition density of port `out_cpu_top` to 20000 transitions per second:

```
set_switching_activity -port out_cpu_top -transition_density 20000
```

- The following command applies a transition density of `1e+06` to all input ports that match the specified pattern:

```
set_switching_activity -port[get_ports "mode*" -filter {port_direction==in}] -
transition_density 1e+06
```

- The following command resets the previously defined activity on all nets that match the specified pattern:

```
set_switching_activity -reset -net[get_nets n23*]
```

- The following command specifies the clock gate ratio for the clock domain `sys_clk`:

```
set_switching_activity -clock sys_clk -integrated_clock_gate_ratio 0.8 -
combinational_clock_gate_ratio 0.5
```

- The following command specifies to set the default switching activity for all other clock domains of the design:

```
set_default_switching_activity -integrated_clock_gate_ratio 1.0 -
combinational_clock_gate_ratio 1.0
```

# set\_twf\_attribute

[-clear_twf_attribute]
```

Specifies static timing analysis information. The command allows you to override timing parameters, such as slew and clock, on desired pins/nets from an existing timing windows file (TWF).

## Parameters

|                           |                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -clear_twf_attribute      |                                                                                                                                                                  |
|                           | Specifies to reset the TWF file values for a specific pin or net. The use model of this parameter is:<br>set_twf_attribute -clear_twf_attribute -pin/-net <name> |
| -clock <i>clock_name</i>  |                                                                                                                                                                  |
|                           | Specifies the clock name. This indicates that the nets and pins that are timing constrained have arrival times (timing windows) caused by this clock.            |
| -clock_edge {rise   fall} |                                                                                                                                                                  |
|                           | Specifies the capturing clock edge direction: rise or fall.                                                                                                      |

|                                                    |                                                                                                                                                                                                           |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-clock_frequency value</code>                |                                                                                                                                                                                                           |
|                                                    | Specifies the clock frequency. You must specify the <code>-clock</code> parameter along with the <code>-clock_frequency</code> parameter to assign the clock for which the frequency needs to be updated. |
| <code>-fall_delay {min:max OR single_value}</code> |                                                                                                                                                                                                           |
|                                                    | Specifies the fall delay for the pin. This parameter is not supported in the static power analysis flow.                                                                                                  |
| <code>-fall_slack {min:max or single_value}</code> |                                                                                                                                                                                                           |
|                                                    | Specifies the fall slack for the pin.                                                                                                                                                                     |
| <code>-fall_slew {min:max or single_value}</code>  |                                                                                                                                                                                                           |
|                                                    | Specifies the fall slew for the pin.                                                                                                                                                                      |
| <code>-net net_name</code>                         |                                                                                                                                                                                                           |
|                                                    | Specifies the net name. The <code>-net</code> and <code>-pin</code> parameters are mutually exclusive.                                                                                                    |
| <code>-pin pin_name</code>                         |                                                                                                                                                                                                           |
|                                                    | Specifies the pin name. The <code>-net</code> and <code>-pin</code> parameters are mutually exclusive.                                                                                                    |
| <code>-reset</code>                                | Resets all specified options back to default values.                                                                                                                                                      |
| <code>-rise_delay {min:max OR single_value}</code> |                                                                                                                                                                                                           |
|                                                    | Specifies the rise delay for the pin. This parameter is not supported in the static power analysis flow.                                                                                                  |
| <code>-rise_slack {min:max OR single_value}</code> |                                                                                                                                                                                                           |
|                                                    | Specifies the rise slack for the pin.                                                                                                                                                                     |
| <code>-rise_slew {min:max OR single_value}</code>  |                                                                                                                                                                                                           |
|                                                    | Specifies the rise slew for the pin.                                                                                                                                                                      |
| <code>-shift_arrival_time time</code>              |                                                                                                                                                                                                           |

Specifies to filter the idle period of the current waveform in the dynamic power analysis flow. This parameter is useful in removing the idle period of the current waveform result with long idle period (small current) before the 1st high current peak because of TWF delay annotation. The parameter allows to offset idle period from the TWF delay values.

The use model is given below:

```
set_twf_attribute -shift_arrival_time 3.0ns
```

The default value is 0ns. The supported time units are s, ms, us, ns, and ps. The default unit is ns. You must specify a positive value only. A positive value means shift right in the time line or add more delay to the original arrival time.

You can specify the `-clock` parameter to limit the changes to a clock domain. In addition, you can further add the `-pin/-net` parameter to limit the changes to a block. The following are examples of shifting different delays to different clock domains because different clocks may have different clock insertion delays at the top level:

```
set_twf_attribute -shift_arrival_time 1.2ns -clock clk_a
set_twf_attribute -shift_arrival_time 2.3ns -clock clk_b
```

If a clock domain is not specified, the delay will be applied to all the specified nets/pins.

**Note:** The final rise/fall delays for the annotated nets/pins after the shift has been applied are reported under the “[Shift Arrival Time Report](#)” section of the detailed TWF Attributes report. This report is generated using the `power_report_twf_attributes detailed` attribute.

The following example illustrates a sample command and report snippet:

**Command:**

```
set_twf_attribute -shift_arrival_time 3.0ns
```

**Report:**

Clock domain annotated

- CK1\_1
- CK1\_2
- CK2\_1
- CK2\_2

| Rise Delay | Fall Delay | Net Name |
|------------|------------|----------|
| 1e-09      | 1e-09      | CK1_1    |
| 1e-09      | 1e-09      | CK1_2    |
| 1e-09      | 1e-09      | CK2_1    |
| ...        |            |          |

```
-type {data | clock}
```

|  |                                                                        |
|--|------------------------------------------------------------------------|
|  | Specifies whether the net or pin is part of the clock or data network. |
|--|------------------------------------------------------------------------|

## Examples

- The following command specifies to use the following TWF attributes for the net `netB1`:  

```
set_twf_attribute -net netB1 -rise_delay 2.1978:2.1978 -rise_slew 0.05:0.05 -rise_slack 0.2741:3.6961
-fall_delay 2.1819:2.1819 -fall_slew 0.05:0.05 -fall_slack 0.237:3.6948 -clock CK1_1 -
clock_frequency 100 -type data
```
- The following commands reset the TWF values for the "DFF11/DFF/Q" pin to default, and then sets the rise/fall delay:  

```
set_twf_attribute -clear_twf_attribute -pin "DFF11/DFF/Q"
set_twf_attribute -pin "DFF11/DFF/Q" -rise_delay 0.35 -fall_delay 0.45 -clock CLK1
```

```
analyze_resistance -threshold 50 -net_threshold
```

# set\_virtual\_clock\_network\_parameters

```
set_virtual_clock_network_parameters
[-help]
[-cell cell_name]
[-clock list_of_clocks]
[-library library_name]
[-max_fanout value]
[-wire_load_model wireload_model]
[-reset]
```

Specifies to estimate power for a virtual clock tree. When the command is specified, the software reports the power of the clock network based on the buffers inserted in the clock tree. It also reports the number of buffers used for implementing the clock tree and the depth of the clock tree.

You can use this command for fast power estimation of clock network power of a pre-CTS netlist.

This command should be invoked before running the `report_power` command.

## Parameters

|                       |                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                 | Outputs a brief description that includes the type and default information for each <code>set_virtual_clock_network_parameters</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command <code>man set_virtual_clock_network_parameters</code> . |
| -cell cell_name       |                                                                                                                                                                                                                                                                                                                       |
|                       | Specifies the name of the buffer or inverter cell that has to be used to build the clock tree.                                                                                                                                                                                                                        |
| -clock list_of_clocks |                                                                                                                                                                                                                                                                                                                       |
|                       | Specifies the list of clocks for which the clock tree needs to be implemented. The default is for all the clocks.                                                                                                                                                                                                     |
| -library library_name |                                                                                                                                                                                                                                                                                                                       |
|                       | Specifies the name of the library which contains the cell.                                                                                                                                                                                                                                                            |
| -max_fanout value     |                                                                                                                                                                                                                                                                                                                       |

|                                              |                                                                                                      |
|----------------------------------------------|------------------------------------------------------------------------------------------------------|
|                                              | Specifies the maximum fanout that the buffer cell can drive.                                         |
| <code>-wire_load_model wireload_model</code> |                                                                                                      |
|                                              | Specifies the wire load model used to compute the wire load model for the nets in the clock network. |
| <code>-reset</code>                          | Resets all specified parameters back to default values.                                              |

## Example

The following command specifies to use the cell `BUFX12`, with a maximum fanout value of `2`, to build a virtual clock tree:

```
set_virtual_clock_network_parameters -cell { BUFX12 } -library typical -max_fanout 2 -
wire_load_model B0X0
```

# write\_power\_constraints

```
write_power_constraints
[-help]
[-out_file filename]
```

Writes out all the power constraints such as the power analysis mode, activity file specifications, simulation period specifications, and so on, into a file. You can use this command at any time during the session to dump out the power commands/ options specified till that point.

You can source this file into other Voltus/Tempus/Innovus session in order to use the same settings.

## Parameters

|                       |                                                                                                                                                                                                                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                 | Outputs a brief description that includes the type and default information for each <code>write_power_constraints</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command <code>man write_power_constraints</code> . |
| -out_file<br>filename | Specifies the output file into which the power constraints are to be written.                                                                                                                                                                                                               |

## Example

```
write_power_constraints -out_file test1.tcl
```

## write\_tcf

```
write_tcf file
[-block block_name]
[-exclude_hier_insts list_of_instances]
[-primary_input]
[-sequential_output]
[-pin]
[-macro_output]
```

Writes out the propagated switching activity information to a toggle count format (TCF) file. The TCF file contains switching activity information, toggle count information, and the probability of the net or pin being in the logic1 state.

You must specify this command before `report_power`.

## Parameters

|                                                                |                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-block <i>block_name</i></code>                          | Specifies to generate the block-level TCF from the top-level design. When specified, it writes out the block-level duty and activity in the generated TCF file.<br><br>The use model of this parameter is:<br><code>write_tcf -pin -block <i>blockname</i> <i>TCF_filename</i></code>                          |
| <code>-<br/>exclude_hier_insts <i>list_of_instances</i></code> | Excludes the specified hierarchical modules or instances when writing out a pin-based TCF. This parameter allows you to ignore the activity generated for the excluded instances.<br><br>The use model of this parameter is:<br><code>write_tcf -pin -exclude_hier_insts<br/>{<i>list_of_instances</i>}</code> |
| <code>-macro_output</code>                                     | Specifies to generate a TCF file that includes all the activities for the macro outputs in the design.                                                                                                                                                                                                         |
| <code>-pin</code>                                              | Specifies to write out pin-based TCF.                                                                                                                                                                                                                                                                          |
| <code>-primary_input</code>                                    | Generates a TCF file that includes only the primary inputs in the design.                                                                                                                                                                                                                                      |
| <code>-sequential_output</code>                                |                                                                                                                                                                                                                                                                                                                |
|                                                                | Generates a TCF file that includes all the activities for the sequential outputs in the design.                                                                                                                                                                                                                |
| <code><i>file</i></code>                                       | Specifies the name of the output TCF file.                                                                                                                                                                                                                                                                     |

## Example

- The following command writes the propagated switching activity information to TCF file `mmm.tcf`:  
`write_tcf mmm.tcf`
- The following command writes a pin-based TCF for the whole design:  
`write_tcf -pin pin_design.tcf`
- The following command writes out a TCF which only includes activity information for the primary inputs and sequential outputs in the design:  
`write_tcf -primary_input -sequential_output Power.tcf`

## analyze\_ir\_paths

```
analyze_ir_paths
[-help]
-clock_period <float>
[-hierarchical_activity_file <string>]
[-max_slack <float>]
[-pre_simulation_period <float>]
-seq_activity <float>
-simulation_period <float>
```

Generates a physical-aware multi-cycle switching activity file containing toggle information of voltage sensitive paths as well as timing critical paths in the design for Tempus Power Integrity analysis. This command generates 'swsrc.txt' file in the run directory, which then is fed back to the software using the [read\\_activity\\_file](#) command.

## Parameters

|                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                               | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-clock_period &lt;float&gt;</code>                         | Specifies the period of dominant clock of the design in library time units. Tempus PI refers to this specified period for multi-cycle activity generation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-<br/>hierarchical_activity_file<br/>&lt;string&gt;</code> | Provides a mechanism for different sequential activity for several partitions in the design. The following is the required format:<br><code>&lt;hierarchical instance 1&gt; &lt;activity&gt;</code><br><code>&lt;hierarchical instance 2&gt; &lt;activity&gt;</code><br>...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>-max_slack &lt;float&gt;</code>                            | Specifies the maximum slack limit in library time units, above which the timing paths are not considered for activity generation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-pre_simulation_period<br/>&lt;float&gt;</code>            | Specifies the pre-simulation duration that will be used by Tempus PI for activity generation.<br><br>This parameter is useful when package model information is read-in using <code>set_package</code> command, as it allows the package oscillations to settle down.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-seq_activity &lt;float&gt;</code>                         | Specifies the activity of sequential endpoints in the design. This value will be used to control the number of IR sensitive paths, along with their fanout cone, to toggle in each cycle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-simulation_period &lt;float&gt;</code>                    | Specifies the simulation period in library time units that Tempus PI dynamic power analysis will use. The larger the simulation period, the more will be the number of paths covered in the analysis.<br><br>The following formula can be used to set the simulation period:<br>$sim\_cycles = (2/seq\_act)*N$ Where,<br><ul style="list-style-type: none"> <li><code>seq_act</code> is the input sequential activity (e.g., 0.05, 0.1 etc.)</li> <li><code>N</code> is the number of nworst paths to be covered per endpoint</li> <li><code>sim_period</code> is equal to the <code>sim_cycles* &lt;time period of dominant clock&gt;</code></li> </ul> It is recommended to have $N \geq 1$ , that is, at least one path per endpoint should be scheduled in the analysis. |

## Examples

- The following command generates the activity file for design with dominant clock of 2GHz, with input sequential activity being 0.1 and simulation duration being 20ns:

```
tempus > analyze_ir_paths -seq_activity 0.1 -simulation_period 20 -clock_period 0.5
```

- The following example specifies different sequential activity for different hierarchical partitions, with 0.2 sequential activity for unspecified partitions and top:

```
tempus > analyze_ir_paths -seq_activity 0.2 -simulation_period 30 -clock_period 0.5 -
hierarchical_activity_file hact.txt
```

Contents of 'hact.txt':

```
hierA/inst1 0.25
```

```
hierB/inst2 0.15
```

- The following command specifies the pre-simulation duration, particularly useful for package oscillations to settle when package models have been read-in:

```
tempus > analyze_ir_paths -seq_activity 0.1 -simulation_period 30 -clock_period 0.5 -
pre_simulation_period 10
```

- [route\\_special Category Attributes](#)

## route\_special Category Attributes

The root attributes in the `route_special` category are:

- [route\\_special\\_allow\\_non\\_preferred\\_direction\\_route](#)
- [route\\_special\\_avoid\\_over\\_core\\_row\\_layer](#)
- [route\\_special\\_block\\_pin\\_connect\\_ring\\_pin\\_corners](#)
- [route\\_special\\_block\\_pin\\_route\\_with\\_pin\\_width](#)
- [route\\_special\\_connect\\_broken\\_core\\_pin](#)
- [route\\_special\\_core\\_pin\\_ignore\\_obs](#)
- [route\\_special\\_core\\_pin\\_merge\\_limit](#)
- [route\\_special\\_core\\_pin\\_length](#)
- [route\\_special\\_core\\_pin\\_length\\_as\\_inst](#)
- [route\\_special\\_core\\_pin\\_max\\_via\\_scale](#)
- [route\\_special\\_core\\_pin\\_refer\\_to\\_follow\\_pin](#)
- [route\\_special\\_core\\_pin\\_reference\\_macro](#)
- [route\\_special\\_core\\_pin\\_site\\_rail\\_width](#)
- [route\\_special\\_core\\_pin\\_snap\\_to](#)
- [route\\_special\\_core\\_pin\\_stop\\_route](#)
- [route\\_special\\_extend\\_nearest\\_target](#)
- [route\\_special\\_jog\\_threshold\\_ratio](#)
- [route\\_special\\_layer\\_preferred\\_direction\\_cost](#)
- [route\\_special\\_layer\\_non\\_preferred\\_direction\\_cost](#)
- [route\\_special\\_pad\\_pin\\_min\\_via\\_size](#)

- `route_special_pad_pin_split`
- `route_special_pad_pin_split_from_center`
- `route_special_pad_ring_use_lef`
- `route_special_secondary_pin_max_gap`
- `route_special_secondary_pin_rail_width`
- `route_special_signal_pin_as_pg`
- `route_special_split_long_via`
- `route_special_pg_pin_as_signal`
- `route_special_target_number`
- `route_special_target_search_distance`
- `route_special_time_limit`
- `route_special_endcap_as_core`
- `route_special_via_through_to_closest_ring`
- `route_special_via_connect_to_shape`
- `route_special_welltap_as_endcap`

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `route_special` category, use the following command:

```
get_db -category route_special
```

## **route\_special\_allow\_non\_preferred\_direction\_route**

```
route_special_allow_non_preferred_direction_route {true | false}
```

*Default:* `false`

*Data\_type:* Boolean

Allows wrong way routing.

**Note:** If the metal1 preferred routing direction is vertical and standard cells have their VDD and VSS pins on layer metal1, sroute will route metal1 wires on horizontal direction to continue extending the followpin connections to core rings by this option

## route\_special\_avoid\_over\_core\_row\_layer

`route_special_avoid_over_core_row_layer layer_name`

*Default:* max layer of standard cell pin

*Data\_type:* String

Specifies the number of layers to avoid routing of block pin and pad pin over the core row area.

## route\_special\_block\_pin\_connect\_ring\_pin\_corners

`route_special_block_pin_connect_ring_pin_corners {true | false}`

*Default:* false

*Data\_type:* Boolean

Specifies that the block wire used for a connection is to have the same width as the pin from which it connects.

## route\_special\_block\_pin\_route\_with\_pin\_width

`route_special_block_pin_route_with_pin_width {true | false}`

*Default:* false

*Data\_type:* Boolean

Specifies that the block wire used for a connection is to have the same width as the pin from which it connects.

## route\_special\_connect\_broken\_core\_pin

`route_special_connect_broken_core_pin {true | false}`

*Default:* false

*Data\_type:* Boolean

When set to 1, `sroute` checks the signal pin, second power pin, and obs, and then breaks the followpin to avoid violations. When set to 0, `sroute` does not check internal geometries and does not break the followpin.

## route\_special\_core\_pin\_ignore\_obs

`route_special_core_pin_ignore_obs {none | placement_blockage | overlap_obs | block_halo}`

*Default:* none

*Data\_type:* Enum

Ignores the specified blockage while connecting the follow pin.

## **route\_special\_core\_pin\_merge\_limit**

`route_special_core_pin_merge_limit value`

*Default:* 0.0

*Data\_type:* Double

Joins follow pin rail gaps smaller than this variable, bigger gaps will remain open. The option is of type *float*.

## **route\_special\_core\_pin\_length**

`route_special_core_pin_length value`

*Default:* 0.0

*Data\_type:* Double

Connects core pins of specified length. The option is of type *float*.

## **route\_special\_core\_pin\_length\_as\_inst**

`route_special_core_pin_length_as_inst {true | false}`

*Default:* false

*Data\_type:* Boolean

Connects core pins whose length equals or is greater than the length of instance.

## **route\_special\_core\_pin\_max\_via\_scale**

`route_special_core_pin_max_via_scale widthPct heightPct`

*Default:* ""

*Data\_type:* String

Controls the length and width of vias at the crossover of core pin rails and stripes. Specify this value as percentages of the width of the via at the top of the stack. Smaller vias leave room for more routing tracks on layers between the vias.

## route\_special\_core\_pin\_refer\_to\_follow\_pin

```
route_special_core_pin_refer_to_follow_pin {true | false}
```

*Default:* false

*Data\_type:* Boolean

If set to `true`, parallel metal followpins are generated based on the existing standard cell pins, when there is no other metal followpin on the standard cell pins.

## route\_special\_core\_pin\_reference\_macro

```
route_special_core_pin_reference_macro macro
```

*Default:* ""

*Data\_type:* String

Uses specified macros as references for followpin creation. The option is of type *string*.

## route\_special\_core\_pin\_site\_rail\_width

```
route_special_core_pin_site_rail_width {{site1 layer11 Width11 layer12 Width12 ...} {site2
layer21 Width21 layer22 Width22 ...} ...}
```

*Default:* ""

*Data\_type:* String

Defines the followpin layer width for the specified site rail for followpin generation. The followpin width defined by this attribute has higher priority than the width of the same layer defined in the macro LEF, but lower than that defined by the `route_special -core_pin_width` parameter.

Following are the values used with this attribute:

- `site`: Specifies the site name defined in the LEF file.
- `layer`: Specifies the name of the layer defined in the LEF file.
- `width`: Specifies the followpin width on the top and bottom sides of the defined site.

## route\_special\_core\_pin\_snap\_to

```
route_special_core_pin_snap_to {M1_pin | opt_routing_track | grid | half_grid}
```

*Default:* M1\_pin

*Data\_type:* Enum

Snaps M2 followpins in the location to save routing tracks in a preventive manner. When set to:

- `M1_pin`: Generated metal2 followpins are snapped to metal1 stdcell pin center.
- `opt_routing_track`: Generated metal2 followpins are snapped to track or half track to save routing tracks.
- `grid`: Generated M2 followpins are snapped to the nearest routing track.
- `half_grid`: Generated M2 followpins are snapped to the nearest half routing track.

## **route\_special\_core\_pin\_stop\_route**

`route_special_core_pin_stop_route {atRowEnd atCellEnd}`

*Default:* RowEnd

*Data\_type:* Enum

Extends the follow pin wire either to the row-end or cell-end.

## **route\_special\_extend\_nearest\_target**

`route_special_extend_nearest_target {true | false}`

*Default:* false

*Data\_type:* Boolean

Extends the nearest target so that it can be connected. The option is of type *bool*.

## **route\_special\_jog\_threshold\_ratio**

`route_special_jog_threshold_ratio value`

*Default:* 10.0

*Data\_type:* Double

Defines the distance ratio between a jogging target and a straight target. The option is of type *float*.

## **route\_special\_layer\_preferred\_direction\_cost**

`route_special_layer_preferred_direction_cost layer1 cost1 layer2 cost2...`

*Default:* ""

*Data\_type:* String

Specifies layer cost of preferred direction. The option is of type `string`.

### **route\_special\_layer\_non\_preferred\_direction\_cost**

```
route_special_layer_non_preferred_direction_cost layer1 cost1 layer2 cost2...
```

*Default:* ""

*Data\_type:* String

Specifies layer cost of non-preferred direction.

### **route\_special\_pad\_pin\_min\_via\_size**

```
route_special_pad_pin_min_via_size viaSizePercent
```

*Default:* 20.0

*Data\_type:* Double

Permits the software to reduce the size of vias at pad pins when changing layers, if there is not enough room for a standard size via.

### **route\_special\_pad\_pin\_split**

```
route_special_pad_pin_split width spacing
```

*Default:* ""

*Data\_type:* String

Splits the width and spacing for wide pad pins.

### **route\_special\_pad\_pin\_split\_from\_center**

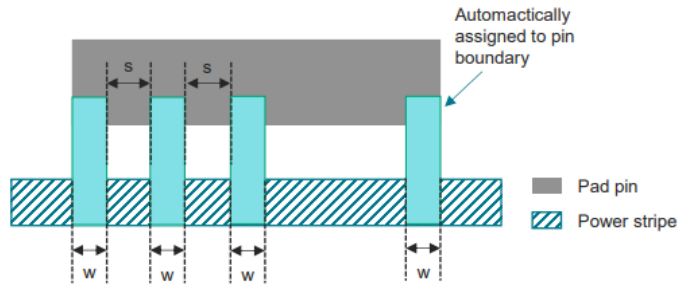

```
route_special_pad_pin_split_from_center {true | false}
```

*Default:* false

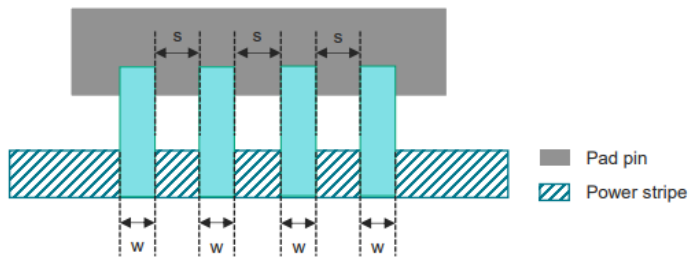

*Data\_type:* Boolean

Splits the width and spacing specified by the `route_special_pad_pin_split` attribute to enable connections to the center of wide pad pins. This parameter must be used with the `route_special_pad_pin_split` attribute. See the examples below:

- ```
set_db route_special_pad_pin_split {w s}
set_db route_special_pad_pin_split_from_center false
```

- `set_db route_special_pad_pin_split {w s}`
`set_db route_special_pad_pin_split_from_center true`

route_special_pad_ring_use_lef

`route_special_pad_ring_use_lef {true | false}`

Default: true

Data_type: Boolean

Splits the width and spacing for wide pad pins.

route_special_secondary_pin_max_gap

`route_special_secondary_pin_max_gap value`

Default: 0.0

Data_type: Double

Specifies variable value for gaps bigger than this value cause level shifter rail to break. The option type is *float*.

route_special_secondary_pin_rail_width

`route_special_secondary_pin_rail_width value`

Default: 0.0

Data_type: Double

Specifies width of followpin rail. The option type is *float*.

route_special_signal_pin_as_pg

```
route_special_signal_pin_as_pg {true | false}
```

Default: false

Data_type: Boolean

Specifies signal pins as PG pins in pad ring creation. The option type is *bool*.

route_special_split_long_via

```
route_special_split_long_via {threshold_value step_value offset_value height_value}
```

Default: 0 0 -1 -1

Data_type: String

Splits vias longer than the specified length (*threshold_value*, in micrometers) into smaller vias with specified center-to-center spacing (*step_value*, in micrometers), left/bottom end offset (*offset_value*, in micrometers) and vertical/horizontal height (*height_value*, in micrometers) values. This is independent of the option *-split_via*.

Note: If the *offset_value* is given as negative, the vias will be placed symmetrically on both ends. The default value of *offset_value* is -1.

route_special_pg_pin_as_signal

```
route_special_pg_pin_as_signal {cellName: pinName}
```

Default: ""

Data_type: String

Lists the cell/pin information NOT extracted from CPF.

route_special_target_number

```
route_special_target_number value
```

Default: 0

Data_type: Integer

Specify number of target to connect. The option type is *int*.

route_special_target_search_distance

```
route_special_target_search_distance dist
```

Default: 0.0

Data_type: Double

Specifies target search distance. The option type is *float*.

route_special_time_limit

```
route_special_time_limit value
```

Default: 0.0

Data_type: Double

Specify time limit (in seconds) that the router is allowed in routing each port. The option type is *float*.

route_special_endcap_as_core

```
route_special_endcap_as_core {true | false}
```

Default: false

Data_type: Boolean

Specifies to treat Endcap macro as core macro. The option type is *bool*.

route_special_via_through_to_closest_ring

```
route_special_via_through_to_closest_ring {true | false}
```

Default: false

Data_type: Boolean

Specifies that a via should connect only to the closest ring layer when multiple rings overlap.

route_special_via_connect_to_shape

```
route_special_via_connect_to_shape {padding|ring|stripe|blockring|blockpin|coverpin|noshape|blockwire|corewire|followpin|iowire}
```

Default: padring ring stripe blockring blockpin coverpin noshape blockwire corewire followpin iowire

Data_type: Enum

Specifies which shapes vias can connect to.

route_special_welltap_as_endcap

`route_special_welltap_as_endcap` *string*

Default: ""

Data_type: String

When used, `route_special` treats the `Welltap` cells as the `Endcap` cells. Additionally, the `ENDCAP`class cells are ignored by default, when connecting the `followpin` wires.

RC Extraction Commands and Attributes

- [extract_parasitics](#)
- [extract_rc Category Attributes](#)
- [read_parasitics](#)
- [report_net_parasitics](#)
- [report_rcdb](#)
- [report_unit_parasitics](#)
- [write_parasitics](#)
- [write_rcdb](#)

extract_parasitics

`extract_parasitics`
[-help]

Extracts resistance and capacitance for the interconnects and stores the results in an RC database. Optionally, an ASCII report file can be generated. Use this command after performing trial routing or final routing, and after setting the [extract_rc Category Attributes](#).

Parameter

- help	Outputs a brief description of the <code>extract_parasitics</code> command. For a detailed description of the command, use the man command: <code>man extract_parasitics</code> .
-----------	---

Example

The following command extracts interconnect resistance and capacitance:

```
extract_parasitics
```

RC database is created.

The `extract_parasitics` command can be followed by the [write_parasitics](#) command to extract the

parasitics from the RC database, and to generate an ASCII report containing the database information. You can find all the extraction reports in the `extLogDir`.

Related Commands

- `read_parasitics`
- `write_parasitics`
- `extract_rc` Category Attributes

extract_rc Category Attributes

The root attributes in the `extract_rc` category are:

- `extract_rc_cap_filter_mode`
- `extract_rc_cerebrus_license_only`
- `extract_rc_compress_rcdb`
- `extract_rc_coupled`
- `extract_rc_coupling_cap_threshold`
- `extract_rc_lef_tech_file_map`
- `extract_rc_local_cpu`
- `extract_rc_pvs_fill`
- `extract_rc_qrc_cmd_file`
- `extract_rc_qrc_cmd_type`
- `extract_rc_qrc_stream_map_file`
- `extract_rc_qrc_run_mode`
- `extract_rc_relative_cap_threshold`
- `extract_rc_shrink_factor`
- `extract_rc_signoff_stream_layer_map`
- `extract_rc_total_cap_threshold`
- `extract_rc_tsv_subckt_file`
- `extract_rc_turbo_reduce`
- `extract_rc_write_def_options_for_signoff_extract`

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `extract_rc` category, use the following command:

```
get_db -category extract_rc
```

extract_rc_cap_filter_mode

```
extract_rc_cap_filter_mode { relative_only | relative_and_coupling | relative_or_coupling }
```

Default: relative_and_coupling

Note: For standalone Quantus extraction, if the process node is 130nm or below, the default value is relative_and_coupling. If the process node is above 130nm, the default value is relative_only.

Data_type: Enum

Specifies the capacitance filtering mode. The filtering modes are conditions which define how to use the extract_rc_coupled and extract_rc_coupling_cap_threshold attribute values, or their combination. Based on the filtering mode specified, the software determines the nets in the design, which will have their coupling capacitance lumped to the ground.

Note: The behavior of the extract_rc_total_cap_threshold attribute is independent of the extract_rc_cap_filter_mode attribute setting. Nets that have a total capacitance value lower than the value specified with the extract_rc_total_cap_threshold attribute will have their coupling capacitances grounded regardless of the extract_rc_cap_filter_mode attribute setting.

You can use one of the following modes:

- **relative_only:** Grounds the coupling capacitance of nets based on the threshold value set by the extract_rc_relative_cap_threshold attribute.
- **relative_and_coupling:** Grounds the coupling capacitance of nets only when it is lower than the threshold value specified with the extract_rc_relative_cap_threshold attribute as well as the extract_rc_coupling_cap_threshold attribute. In this mode, you enforce maximum restriction on grounding the coupling capacitances.
- **relative_or_coupling:** Grounds the coupling capacitance of nets if it is lower than the threshold value specified with one of the extract_rc_relative_cap_threshold or extract_rc_coupling_cap_threshold attributes.

Related Command

- [extract_parasitics](#)

extract_rc_cerebrus_license_only

```
extract_rc_cerebrus_license_only {true | false}
```

Default: false

Data_type: Boolean

This attribute is applicable to the Cerebrus-Quantus flow.

When set to `true`, only the Cerebrus license will be considered and Innovus will not fall back to use Quantus (QTS) license when Cerebrus license(s) is/are not available. By default, the attribute is set to `false`, which means the regular QTS license will be considered when Cerebrus license(s) is/are not available.

extract_rc_compress_rcdb

```
extract_rc_compress_rcdb {true | false}
```

Default: `false`

Data_type: Boolean

Generates compressed RCDB data.

Note: This functionality reduces the disk usage but leads to marginal increase in run time.

Related Command

- `extract_parasitics`

extract_rc_coupled

```
extract_rc_coupled {true | false}
```

Default: `true`

Data_type: Boolean

Separately outputs grounded and coupling capacitance. The 0 value of this attribute is typically used for static timing analysis. Signal Integrity analysis requires the coupled mode.

extract_rc_coupling_cap_threshold

```
extract_rc_coupling_cap_threshold file_name
```

Default: `0.1`

Data_type: Double

Specifies the threshold value (in femtoFarads) that determines when the extractor lumps a net's coupling capacitance to ground. This attribute is applicable only when the `extract_rc_coupled` attribute is set to 1. The software decouples the coupling capacitance of nets when the total coupling capacitance between the pair of nets is lower than the threshold specified with this attribute. The actual decoupling also depends on the setting of the `extract_rc_cap_filter_mode` attribute.

Related Command

- [extract_parasitics](#)

extract_rc_lef_tech_file_map

`extract_rc_lef_tech_file_map filename`

Default: ""

Data_type: String

Specifies the location of the optional layer map file for the Standalone Quantus QRC engine.

Note: If used, the layer map file must be in the Common Command Language (CCL) format. The following is an example of the layer map file format:

```
extraction_setup \  
-technology_layer_map \  
# <LEF/DEF Name> #<Tech File Name>  
M1 METAL_1 \  
VIA1 VIA_1 \  
M2 METAL_2 \
```

Note: For cell-level Quantus layermap, the DEF/LEF layer names are case sensitive, but ICT layer names are case-insensitive.

Related Command

- [extract_parasitics](#)

extract_rc_local_cpu

`extract_rc_local_cpu number_of_cpus`

Default: 0

(As specified in the [set_multi_cpu_usage](#) -local_cpu setting.)

Data_type: Integer

Specifies the number of CPUs to be used for IQuantus extraction. This attribute is only applicable for the IQuantus extraction engine. When specified, it overrides the `set_multi_cpu_usage -local_cpu` option for IQuantus.

Related Command

- `extract_parasitics`

extract_rc_pvs_fill

```
extract_rc_pvs_fill {true | false}
```

Default: false

Data_type: Boolean

When this attribute is set to true, the PVS fill data attached to the Innovus database is sent to Quantus so that the effects of the fill data are extracted. This attribute only affects signoff Quantus extraction. It has no effect on tQuantus or iQuantus extraction done inside Stylus. This attribute requires that either the `extract_rc_qrc_stream_map_file` attribute or the `extract_rc_signoff_stream_layer_map` attribute is specified.

extract_rc_qrc_cmd_file

```
extract_rc_qrc_cmd_file filename
```

Default: ""

Data_type: String

Specifies the user-created Quantus command file to be used for running Standalone Quantus QRC. This command file should be in the new CCL syntax.

Note: This attribute is only valid if `extract_rc_qrc_cmd_type` `partial` or `custom` is selected.

Related Command

- `extract_parasitics`

extract_rc_qrc_cmd_type

```
extract_rc_qrc_cmd_type {auto | partial | custom}
```

Default: auto

Data_type: Enum

Specifies whether to derive the settings for running Quantus from the software settings, or from user-created command file using the `extract_rc_qrc_cmd_file` attribute.

This attribute supports the following values:

- **auto:** Derives the Quantus settings automatically from the software parameter settings.
Note: In this mode, the `extract_rc_lef_tech_file_map` attribute is required to be specified.
- **partial:** Appends user commands from the `qrcCmdFile` to the settings derived from the software parameter settings. You must provide the partial mode command file in CCL syntax. Use the partial command file only when you add extraction directives for those options that cannot be set in software. Following are some important restrictions:
 - Do not specify the following options in the partial mode command file:
 - Threshold setting
 - Coupled/decoupled mode
 - Quantus Techfile (s)
 - Operating Temperature
 - Do not specify `"-directory_name"` and `"-temporary_directory_name"` and `"-file_name"` in `output_setup` section of the command file
 - Do not specify output file using `output_setup -file_name` command in partial command file

There is no checking for syntax or content of this file, and it will be appended as is to the automatically created Quantus command file.

- **custom:** Gets the complete Quantus settings from the user-created command file. Except for input and output, no settings from software parameters are used. You must provide the complete Quantus command file in CCL syntax.
Following are some important restrictions:
 - Do not specify an input DEF/OA DB in the custom mode command file
 - Do not specify `"-directory_name"` and `"-temporary_directory_name"` in `output_setup` section of the command file.
 - Specify output SPEF with the following convention for the name: `<design>.spef`.
In MMMC, the output SPEF files will be
named: `<design>_<corner>_<Temperature>.spef`. Here "design" refers to the top cell name.

Note: Do not prefix or postfix the output file name.

- Specify the Quantus Techfile(s) to be used. In MMMC, the corner names should match the names used in the `create_rc_corner` command
- Provide Quantus Techfile layer mapping information in custom command file
- If GDS is provided for cell contents, provide a Quantus Techfile to GDS layer number matching

Note: There is no checking for syntax or content of the command file prior to running the extraction. The command file will be used as is. If the output file is not specified correctly, the resulting parasitic file will not be read into the Tempus RC database.

Related Command

- `extract_parasitics`

extract_rc_qrc_stream_map_file

`extract_rc_qrc_stream_map_file filename`

Default: ""

Data_type: String

This attribute is specified only when `-pvs_fill` parameter is set to true. When the `extract_rc_pvs_fill` attribute is set to true, a Quantus stream/oasis map Tcl command is required to map the PVS layer/dtype data to the corresponding Quantus layers.

If the `pvs_fill.data` is generated based on (GDS), the map file should be in the following format:

```
#layer gds_layer gds_dtype
<layer_name> <layer_number> <data_type>
...
```

If the `pvs_fill.data` is generated based on OASIS, the map file should be in the following format:

```
#layer oasis_layer oasis_dtype
<layer_name> <layer_number> <data_type>
...
```

Where,

- `layer_name` is the layername in the design
- `layer_number` is the layer ID in the GDS/OASIS file
- `data_type` is the datatype specified in the GDS/OASIS file

For example,

```
M1  31  0
M1  31  1
M2  32  0
M2  32  1
```

Related Command

- `extract_parasitics`

extract_rc_qrc_run_mode

`extract_rc_qrc_run_mode {concurrent | sequential}`

Default: `concurrent`

Data_type: Enum

Specifies the Quantus run mode in MMMC designs.

Note: For MMMC designs, in Quantus partial command type, do not specify the output SPEF file name and RC corner name in the command file to run Quantus in concurrent or sequential mode. For MMMC designs, in Quantus custom command type, do not specify the output SPEF file name and RC corner name together in the command file. Quantus sequential mode is not supported in custom command type.

This attribute supports the following values:

- `concurrent` : Runs Quantus for all active corners concurrently.
- `sequential` : Runs Quantus for all active corners sequentially.

Related Command

- `extract_parasitics`

extract_rc_relative_cap_threshold

`extract_rc_relative_cap_threshold value`

Default: `1.0`

Data_type: Double

Sets a ratio threshold value that determines when the extractor lumps a net's coupling capacitance to ground. This attribute is applicable only when the `extract_rc_coupled` attribute is set to 1. If the total coupling capacitance between a pair of nets is less than the percentage (specified with this attribute) of the total capacitance of the net with the smaller total capacitance in the pair, the coupling capacitance between these two nets will be considered for grounding. The actual decoupling also depends on the setting of the `extract_rc_cap_filter_mode` attribute.

The range of this value is 0 to 1.

Related Command

- `extract_parasitics`

extract_rc_shrink_factor

`extract_rc_shrink_factor shrink_factor_value`

Default: 1.0

Data_type: Double

Sets the value by which the software shrinks the design before extraction. The shrink factor is used only for extraction calculations. It does not change the actual design. This attribute must only be used when restoring design.

Note: This attribute is not recommended for newer technologies where shrink factor is defined in the Quantus QRC techfiles or capacitance tables.

Related Command

- `extract_parasitics`

extract_rc_signoff_stream_layer_map

`extract_rc_signoff_stream_layer_map file_name`

Default: ""

Data_type: String

This attribute is specified only when the `extract_rc_pvs_fill` attribute is set to `true`. When the `extract_rc_pvs_fill` attribute is set to `true`, a Quantus stream/oasis map Tcl command is required to map the PVS layer/dtype data to the corresponding Quantus layers.

If the `pvs_fill.data` is generated based on stream (GDS/OASIS), the map file should be in the following format:

```
#layer gds_layer gds_dtype use-type color-ID
<layer_name> <layer_number> <data_type> <use-type> <color-ID>
...
```

Where,

- `layer_name` is the LEF layername in the design
- `layer_number` is the layer ID in the GDS/OASIS file

- `data_type` is the datatype of the layer in the GDS/OASIS file
- `use_type` is the keyword for identifying the use of the data. The valid values are:
 - `gray`: library data in the GDS/OASIS file
 - `fill`: regular metal fill data in the GDS/OASIS file
 - `active`: active metal fill data in the GDS/OASIS file
- `color-ID` is the color ID. Use “1” or “2” if the layer is colored, or use hyphen “-” if the layer is not colored

For example,

```
M1 31 0 gray -
M1 31 1 fill -
M2 32 0 gray -
M2 32 1 fill -
```

Related Command

- `extract_parasitics`

extract_rc_total_cap_threshold

`extract_rc_total_cap_threshold value_in_fF`

Default: 0.0

Data_type: Double

Specifies the threshold value (femtoFarads) that determines when the extractor lumps a net's coupling capacitance to ground. This attribute is applicable only when the `extract_rc_coupled` attribute is set to 1. The software grounds the coupling capacitances for the nets which have a total capacitance value less than the value specified with this attribute.

Related Command

- `extract_parasitics`

extract_rc_tsv_subckt_file

`extract_rc_tsv_subckt_file filename`

Default: ""

Data_type: String

Specifies the name of the Through Silicon Via (TSV) subckt file to be used. The file contains the .subckt model information for TSV. The file has a Spice format. A sample file is shown below.

```
.subckt TSV top bottom
R1 top n2 0.03075
R2 n2 bottom 0.03075
C1 n2 0 28f
.ends
```

Where,

`top` and `bottom` refer to the terminal nodes on the top and bottom layers of the TSV

`n2` is the internal node between the top and bottom layers

`R1 top n2 0.03075` means that a resistor with a resistance of `0.03075 Ohms` is added between the `top` and `n2` nodes

`R2 n2 bottom 0.03075` means that a resistor with a resistance of `0.03075 Ohms` is added between the `bottom` and `n2` nodes

`C1 n2 0 28f` means that a ground capacitance of `28 fF` is added on the `n2` node

Note: The IQuantus engine might not keep the subckt connectivity as it is. The optimization of RES network will remove node `n2` (if there is no other connections) and keep a single resistor between the top and bottom nodes with an accumulated resistance. For example, in the above example, the accumulated resistance will be `0.0615 Ohms`. Capacitance will also be moved to a “higher layered node”. In the above example, this layer is `top`.

Related Command

- `extract_parasitics`

extract_rc_turbo_reduce

```
extract_rc_turbo_reduce {0 | 1 | auto}
```

Default: `auto`

Data_type: Enum

Controls the turbo reduction feature for Standalone Quantus QRC extraction. You can set the following options:

- `auto`: When set to `auto`, the software automatically turns on turbo reduction and proceeds when the required Quantus QRC license is available. However, if the required Quantus QRC license is not installed in the license server, the software automatically turns off Turbo reduction and proceeds with a warning message. If the license is installed in the license server but temporarily

not available, then two scenarios are possible. First, if the license wait mode is not turned on, then Quantus will look for the license right away and error out because the license is not available. Second, if the license wait mode is turned on, then Quantus will wait and check for the license periodically until timeout. If the license is available before the timeout, turbo reduction will be performed but if the license is not available before timeout, QRC will error out.

- 1: When set to `true`, the turbo reduction engine is `on`. However, if the required Quantus QRC license is not installed in the license server, then standalone Quantus will error out with a message and the run will stop. It is because setting the option to true means the user really wants to perform turbo reduction.
- 0: The turbo reduction engine is switched `off`.

For details, see the table below.

Behavior of Turbo Reduction

Option Selected – extract_rc_turbo_reduction {1 0 auto}	Availability of Quantus QRC AA License		
	<u>Quantus QRC AA Installed and Available</u> (IQRC gets the license right away even in the wait mode because sufficient licenses are available in the license server)	<u>Quantus QRC AA Installed but not Available</u> (If license wait mode is not turned on, then Quantus looks for the license. If the wait mode is turned on and if the license is temporarily not available, then IQRC waits and checks for the license periodically until timeout.)	<u>Quantus QRC AA Not Installed on License Server</u>
auto	perform turbo reduction	1. error out if wait mode is not on or if the specified wait time is exceeded 2. perform turbo reduction if wait mode is on and the license is available within the specified time.	print warning and do not perform turbo reduction
1	perform turbo reduction	error out	error out because the user explicitly wants to use turbo reduction
0	do not perform turbo reduction	do not perform turbo reduction	do not perform turbo reduction

extract_rc_write_def_options_for_signoff_extract

extract_rc_write_def_options_for_signoff_extract *list_of_def_options*

Default: ""

Data_type: String

Specifies the list of `write_def` options for signoff extraction.

For signoff extraction, `set_db extract_rc_engine post_route set_db extract_rc_effort_level signoff`, the software internally calls the `write_def` command. However, in some specific scenarios, you need to provide additional options for the `write_def` command. Use this attribute to provide the list of `write_def` options to be included.

When this attribute is set, `extract_parasitics` will include these options while calling the `write_def` command.

Related Command

- `extract_parasitics`

read_parasitics

```
read_parasitics
[-help]
[-force]
[-keep_star_node_locations]
{[[[[-rc_corner string]]]]}
[-via_variation_file viaVariationFile]
```

Reads SPEF and RCDB-based RC parasitics information and already created RCDBs in the software. For hierarchical designs, use this command to read top-level as well as block-level parasitic information.

Note: The following are important aspects to be considered for using this command:

- The RCDB parasitic file must have the `.rcdb.d` extension.
- The RCDB-based parasitic data that is provided as input to this command must be the one that was saved in the same major release of the software. The command will not read the RCDB data saved in a previous release. For example, if you provide RCDB saved in the 10.1.x release of the software as input to the `read_parasitics` command in the 11 software release, then it cannot be read.
- Only the RCDB parasitic data on systems that are same as those used for saving the data can be read. For example, if the data is saved on Linux in 64-bit mode, you can only restore it on Linux 64-bit mode.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>read_parasitics</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man read_parasitics</code> .
<code>-force</code>	Allows reading of parasitic data even when block level RCDB/ SPEF is missing for a corner. Note: This parameter is only applicable for hierarchical designs. It is required that the top cell should have parasitic data specified for all the active RC corners.
<code>-keep_star_node_locations</code>	Specifies whether or not to read the *N statements in the SPEF file. The *N statements define the location of the RC nodes. When this parameter is specified, the *N statements are read and when it is not specified, the *N statements are ignored.

`-rc_corner` *list of RCcorner specific RCDBs/SPEFs for hierarchical design | RCcorner specific RCDB/SPEF*

Specifies the RC corner name along with a corner-specific RCDB or SPEF for both top and block levels. For hierarchical designs, this parameter lists the corner-specific SPEFs/RCDBs for top and block levels.

To read multi-value SPEFs, specify the `spef_list`. The `spef_list` provides the list of SPEFs and `spef_field` provides the corresponding SPEF fields to read for the specified RC corner.

In the example below, for RC corner RC1, `spef_field 2` from `<spef1>` and `spef_field 3` from `<spef2>` will be read.

```
read_parasitics \
-rc_corner RC1 {spef_list {<spef1> <spef2>} spef_field {2 3}}
```

Similarly, you can specify this for multiple RC corners.

```
-rc_corner RC2 {spef_list {<spef3> <spef4>} spef_field {1 3}} \
-rc_corner RC3 .... \
```

Note: A corner-specific RCDB parasitic file can only be provided as input to the RC corner for which it was generated. It cannot be provided as input to other RC corners.

`-via_variation_file` *viaVariationFile*

Specifies the name of the file for modeling via variation. The contents of the file include all the via layer names with the corresponding MEAN_SHIFT and STDDEV so that all the VIA resistance in SPEF can be mapped to their own variation multiplier. This option is used to specify the via_variation file only when the design has a single corner.

For example,

```
read_parasitics
-rc_corner rcCornerName \
-via_variation_file viaVariationFileName
```

Examples

- The example below is for hierarchical design with Top (T), Block 1(B1) and Block 2(B2), and two active RC corners, C1 and C2.
 - The following command specifies the RC corner names along with corner-specific RCDB

and SPEF for both top and block levels:

```
tempus> read_parasitics \  
-rc_corner C1 Top_C1.spef Block1_C1.spef Block2_C1.spef.gz \  
-rc_corner C2 Top_C2.rcdb.d Block1_C2.spef Block2_C2.rcdb.d
```

- The example below is for hierarchical design with Top (T), Block 1(B1) and Block 2(B2), and three active RC corners, C1, C2, and C3.
 - The following command specifies the multi-corner RCDB database to be read for both top and block levels and a single RCDB will be generated for the complete design:

```
tempus> read_parasitics \  
-rc_corner C1 Top_C1.spef.gz \  
-rc_corner C2 Top_C2.compressed.rcdb.d \  
-rc_corner C3 Top_C3.rcdb.d
```

Related Commands

- `extract_parasitics`
- `report_net_parasitics`
- `report_unit_parasitics`
- `write_parasitics`

report_net_parasitics

```
report_net_parasitics
[-help]
net_name
-rc_corner rc_corner_name
[-out_file output_file_name]
```

Reports the RC parasitics of the specified net.

The `report_net_parasitics` command reports a list of attackers in the order of worst coupling capacitance by default. The software determines and reports the probable top N worst attackers for a victim. The command output will show worst coupling capacitance, in addition to RC parasitics.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>report_net_parasitics</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_net_parasitics</code> .
<code>-out_file</code> <code>output_file_name</code>	Specifies the name of the output file.
<code>-</code> <code>rc_corner rc_corner_name</code>	Specifies the RC corner name for which the RC parasitics are to be reported.
<code>net_name</code>	Specifies the name of the net for which the RC parasitics are to be reported.

Example

- The following command reports the RC parasitics for net, NET1 for RC corner, rc_best:

```
report_net_parasitics -rc_corner rc_best NET1
```

```
Net: NET1
```

```
RC Corner: rc_best
```

```
Total Cap = 0.473082 ff
```

```
Total Res = 2.104041 ohms
```

```
Total XCap = 0.334035 ff
```

```
Cap Distribution:
```

```
Total Ground Cap = 0.139046 ff
```

```
XCap With Nets:
```

```
NET3 = 0.059964 ff
```

```
NET4 = 0.040277 ff
```

```
NET5 = 0.233794 ff
```

- The following command reports the RC parasitics for the specified RC corner and net named

```
E_CN541_ds_dtin_10:
```

```
report_net_parasitics -rc_corner corner_worst_RCMAX E_CN541_ds_dtin_10
```

```
Net: E_CN541_ds_dtin_10
```

```
RC Corner: corner_worst_RCMAX
```

```
Total Cap = 10.881560 ff
```

```
Total Res = 294.239014 ohms
```

```
Total XCap = 4.972800 ff
```

```
Cap Distribution:
```

```
Total Ground Cap = 5.908761 ff
```

```
XCap With Nets:
```

```
DATA_SAMPLE_MUX_INST/E_N27_n_39 = 2.341080 ff
```

```
scan_in2 = 2.208500 ff
```

```
E_IG_N67E_N231_digit_5_ = 0.423220 ff

report_rcdb

report_rcdb
[-help]
dir_name

Displays the contents of the RCDB being read.

Note:

1. This command is supported only for reading flat single RCDB. Multiple RCDB's cannot be read simultaneously using this command.
2. The RCDB being read must be generated on the same platform and architecture on which it is being read. For example, if you have generated the RCDB on Linux platform, then the `report_rcdb` command cannot report its content on the IBM AIX platform. Similarly, an RCDB generated on a 64-bit system cannot be reported on a 32-bit system.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>report_rcdb</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_rcdb</code> .
<i>dir_name</i>	Specifies the location of the RCDB directory.

Example

- The following command reports the contents of the RCDB being read in the `report.rcdb.d` directory:

```
write_rcdb report.rcdb.d
report_rcdb report.rcdb.d/

RCDB VERSION           : 11.15
OS-bit                 : 64
OS-endianness          : little-endian
RCDB Compression       : off
RCDB Source            : Innovus
DESIGN                 : dtmf_recvr_core
RC-Corners:            : corner_worst_RCMAX, corner_worst_RCMIN
Coupled                : yes
Node-loc               : no
Statistical            : no
```

Related Commands

- `extract_parasitics`
- `read_parasitics`
- `write_parasitics`
- `write_rcdb`

report_unit_parasitics

```
report_unit_parasitics
[-help]
-layer metal_layer_name
-rc_corner rc_corner_name
[-space wire_space_in_um]
[-via_res via_resistance]
[-width wire_width_in_um]
```

Reports unit parasitics for individual metal layers and vias. The report prints the per unit resistance and capacitance for the specified layer. The resistance values are reported in ohms per micron for min width and min spacing of the layer. The capacitance values are reported in femtofarad (fF) per micron for min width and min spacing of the layer.

Via parasitics are printed considering the layer mentioned in the command as the lower layer of the via. The default via specified in the LEF file will be considered in this case.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>report_unit_parasitics</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man report_unit_parasitics</code> .
-layer metal_layer_name	Specifies the name of the metal layer for which the unit parasitics are to be reported. This parameter is required.
-rc_corner rc_corner_name	Specifies the name of the RC corner for which the unit parasitics are to be reported. This parameter is required.
-space wire_space_in_um	Specifies the wiring space in microns. <i>Default:</i> minimum spacing
- via_res via_resistance	When this parameter is specified, the resistances of all vias, whose upper layer is specified using the <code>-layer</code> parameter, are reported.
-width wire_width_in_um	Specifies the wiring width in microns. <i>Default:</i> minimum width

Examples

- The following command reports the unit parasitics for metal layer, `Metal5`, for the specified RC corner, `rc_worst`:

```
report_unit_parasitics -layer Metal5 -rc_corner rc_worst
```

The software gives the following information:

```
Unit parasitics for layer Metal5 (in fF,ohm)
RC-Corner = rc_worst
Cap = 0.213204
Res = 0.900873
Parasitics for default Via "VIA5_0_VH"
Via Cap = 0.017901
Via Res = 8.859576
```

- The following commands reports the unit parasitics for `Metal5` with spacing two times the minimum spacing:

```
report_unit_parasitics -layer Metal5 -rc_corner rc_worst -space [expr 2 * [dbGet [dbGet
head.layers.extName Metal5 -p].minSpacing]]
```

The software gives the following information:

```
Unit parasitics for layer Metal5 (in fF,ohm)
RC-Corner = rc_worst
Cap = 0.188657
Res = 0.900873
Parasitics for default Via "VIA5_0_VH"
Via Cap = 0.017901
Via Res = 8.859576
```

- The following commands reports the unit parasitics for `Metal5` with width two times the minimum width:

```
report_unit_parasitics -layer Metal5 -rc_corner rc_worst -width [expr 2 * [dbGet [dbGet
head.layers.extName Metal5 -p].minWidth]]
```

The software gives the following information:

```
Unit parasitics for layer Metal5 (in fF,ohm)
RC-Corner = rc_worst
Cap = 0.198657
Res = 0.555333
Parasitics for default Via "VIA5_0_VH"
Via Cap = 0.017901
Via Res = 8.859576
```

- The following commands reports the unit parasitics for vias with top layer of Metal5:

```
report_unit_parasitics -layer Metal5 -rc_corner rc_worst -via_res
```

The software gives the following information:

```
Unit parasitics for layer Metal5 (in fF,ohm)
```

```
RC-Corner = rc_worst  
Cap = 0.213204  
Res = 0.900873
```

```
Parasitics for default Via "VIA5_0_VH"
```

```
Via Cap = 0.017901  
Via Res = 8.859576  
Other Via res  
VIA45_1C 8.859576

Related Commands

- `extract_parasitics`
- `report_net_parasitics`
- `read_parasitics`
- `write_parasitics`

write_parasitics

```
write_parasitics  
[-help]  
[-exclude_ilm]  
[-no_resistances]  
[-use_eeq_cell_with_liberty_info]  
{{{-speg_file file_name} [-exclude_nets_file file_name | -include_nets_file file_name | -  
net_name list_of_nets]} } [-view view_name | -rc_corner rc_corner_name] [-cap_unit {pf | ff}]
```

Reads the parasitic database and outputs the parasitics in the Standard Parasitic Exchange Format (SPEF).

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>write_parasitics</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man write_parasitics</code> .
<code>-cap_unit {pf ff}</code>	Specifies the unit of capacitance as <code>fF</code> or <code>pF</code> in the output SPEF file. <i>Default:</i> <code>pf</code>
<code>-exclude_ilm</code>	Writes out only the top-level SPEF while excluding the ILM parasitics. For example, <code>write_parasitics -exclude_ilm -spef abc.spef -rc_corner corner1</code>
<code>-exclude_nets_file file_name</code>	Specifies the name of the file that contains nets to be excluded from the output file.
<code>-include_nets_file file_name</code>	Specifies the name of the input file that contains the net names to be extracted. <i>Default:</i> Extracts all net names
<code>-net_name list_of_nets</code>	Specifies the names of the nets to be written in the SPEF file. <i>Default:</i> Writes all nets
<code>-no_resistances</code>	Generates a SPEF file without the resistance information. The SPEF file generated by this parameter can only be used to improve the performance of third-party simulator tools in early stages of the design. Caution: Most tools expect the resistance information to be present in the SPEF file for performing extraction. Therefore, SPEF files with no resistance information should not be used with ostrich for RC correlation.
<code>-rc_corner rc_corner_name</code>	Specifies the RC corner that is used to generate the parasitic output file in the multi-corner flow.
<code>-spef_file file_name</code>	Specifies the name of the SPEF output file.
<code>-use_eeq_cell_with_liberty_info</code>	Writes EEQ master cell in case the EEQ cells are present.
<code>-view view_name</code>	Specifies that the RC corner associated with the specified view is used to generate the output SPEF file in the multi-corner flow.

Examples

- Reads the parasitic database created during RC extraction and writes the interconnect capacitance in the SPEF format to the file `TOPCHIP_SP.spef` for RC corner, `corner1`:

```
write_parasitics -rc_corner corner1 -spef_file TOPCHIP_SP.spef
```

- Reads the parasitic database created during RC extraction for the view, `view1`:

```
write_parasitics -view view1
```

write_rcdb

`write_rcdb`
`[-help]`
`out_dir`

Saves the parasitic data that you specify in a Tempus session. Use the `read_rcdb` command to restore the parasitic data.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for the <code>write_rcdb</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man write_rcdb</code> .
<code>out_dir</code>	Specifies the location of the RCDB directory. The directory name should follow the <code>*.rcdb.d</code> format.

Example

- The following example writes the parasitic data to a directory called `myparasitics.rcdb`:
`write_rcdb myparasitics.rcdb.d`

[[ > | >> ]]
```

Allows the software to perform Spice jitter analysis on a clock network using user-specified EIV database. The EIV database stores the effective instance voltages (EIV) per cycle for different instances in the design.

The software reads in the EIV files and identifies the worst two consecutive cycles for each instance where the voltage variation is maximum. The voltage levels from these identified cycles are used as the corresponding supplies for different instances in the generated Spice deck - which is simulated using the Spectre simulator to compute the cycle-to-cycle IR induced jitter.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

<code>-eiv_cycle_interval</code> <integer>	Allows the software to run the <code>analyze_jitter</code> command natively for EIV cycles with the specified cycle interval.
<code>-eiv_end_time</code> <i>float</i>	Specifies the end time for EIV reading. The voltages specified in the EIV database for time-stamps beyond this value are ignored. <i>Default:</i> The last time-stamp from EIV file is considered as the end time.
<code>-eiv_file</code> <i>string</i>	Specifies the effective instance voltage files for accounting IR Drop in jitter computation.
<code>-eiv_num_cycle</code> <integer>	Runs the <code>analyze_jitter</code> command natively for the specified number of EIV cycles.
<code>-eiv_power_ground</code> <i>string</i>	Specifies the power and ground net names for each EIV file specified using the <code>-eiv_file</code> parameter. For example, "vdd1 vss1 vdd2 vss2", vdd1 and vss1 are for first and vdd2 and vss2 for the second EIV file defined using the <code>-eiv_file</code> parameter.
<code>-eiv_start_cycle</code> <integer>	Runs the <code>analyze_jitter</code> command natively from the starting EIV cycle.
<code>-eiv_start_time</code> <i>float</i>	Specifies the start time for EIV reading. The voltages specified in the EIV database for time-stamps before this value are ignored. <i>Default:</i> The first time-stamp from the EIV file is considered as the start time.
<code>-enable_spectre_x</code>	Enables spectreX license checkout when launching Spectre.
<code>-force_delete_output_dir</code>	Completely removes the directory specified by the user using the <code>-out_dir</code> parameter.
<code>-from</code> <i>string</i>	Creates a Spice deck of the clock network starting from the specified pin.
<code>-from_fall</code> <i>string</i>	Creates a Spice deck of the clock network starting from the falling transition of the specified pin.
<code>-from_rise</code> <i>string</i>	Creates a Spice deck of the clock network starting from the rising transition of the specified pin.

<code>-level {true false}</code>	When set to <code>true</code>, the software traverses down all the way till it hits the clock pin of a flipflop, or any stop point specified with the <code>-to</code> parameter, or when it passes depth specified with the <code>-depth</code> parameter. <i>Default:</i> <code>false</code>
<code>-levels_combine integer</code>	Specifies the number of levels, going up from the leaf nodes, at which the sub-trees can be combined. By default, the whole clock network is simulated as a single Spice netlist for jitter analysis. But for large networks, running single simulation can result in significant increase in the run time. When you use this parameter, the software breaks down the clock network into multiple sub-trees, and runs Spice simulations in parallel. For the following values, the behavior is as follows: • 0: Divides the network such that the path traversed from a clock source to each leaf node is part of a separate sub-tree. • 1: Each sub-tree contains the path traversed from a clock source to one-level up of a leaf node. And all the leaf nodes in the fanout of the identified level are part of this sub-tree, and so on. Note: The <code>-max_spectre_lic</code> parameter must have a value greater than 1 to achieve this parallelization.
<code>-lsf_job_string string</code>	Specifies the handle to the farm job for launching simulation.
<code>-max_spectre_lic integer</code>	Specifies the number available Spectre licenses that can be utilized for simulation parallelization. <i>Default:</i> 1 license is assumed to be available, thereby disabling parallelization.
<code>-mode {period cycle_to_cycle } time_interval_error}</code>	Runs the <code>analyze_jitter</code> command natively for the specified mode type. <i>Default:</i> <code>period</code>
<code>-model_file string</code>	Specifies the path of Spice model files that contain the Spice model information.

<code>-level {true false}</code>	When set to <code>false</code>, the Spice deck is generated only for the traced paths starting from the <code>-from</code> pin and ending at the <code>-to</code> pin. It does not traverse through the fanout branches that do not lead to the <code>-to</code> specified pin. When set to <code>true</code>, traversal occurs through the whole fanout cone of the <code>-from</code> pin till it hits a clock pin of a flop, or any stop point specified with the <code>-to</code> parameter <i>Default:</i> <code>false</code>
<code>-out_dir string</code>	Specifies the output directory for the created Spice decks and the simulation output files. <i>Default:</i> <code>tempus_pathsim</code>
<code>-run_simulation</code>	Enables jitter simulation, in addition to generating the Spice deck.
<code>-skip_stage_fanout string</code>	Accepts two positive integers in the format "N1 N2", and scans up to N1 stages in the fanin cone of each endpoint. The software skips the segments where a stage is found to have a fanout greater than N2. For example, a jitter path <code>Clk_root1 -> ... -> B3 -> B2 -> B1 -> Reg2</code>, B2 and B1 are the last 2 levels. 1) Assume B1's fanout is 100 and B2's fanout is 80, then • When N1 = 1, N2 = 80, B1 will be skipped. • When N1 = 2, N2 = 100, B1 will be skipped • When N1 = 2, N2 = 80, B2 & B1 will be skipped Note: B2 will always cause B1 to be skipped even when B1's fanout is less than 80. So the reduction continues to increase when the level changes from 1 to 2. 2) Assume B1's fanout is 80, and B2 fanout is 100, then, • When N1 = 2, N2 = 90, both B2 and B1 will be skipped.
<code>-spectre string</code>	Specifies the location of the Spectre path.
<code>-spectre_cmd_options string</code>	Specifies the command line options for Spectre.
<code>-subckt_file string</code>	Specifies the file(s) containing subckt definitions of all the instances for which the Spice simulation needs to be performed.

<code>-through string</code>	Creates the Spice deck of a clock network that starts from the <code>-to</code> pin and traverses through the specified pin(s).
<code>-to string</code>	Creates the Spice deck of a clock network terminating at the specified pin(s).
<code>> filename</code>	Redirects the <code>-run_simulation</code> output to a file.
<code>>> filename</code>	Appends the <code>-run_simulation</code> output to a file.

Examples

- The following command generates the Spice deck for jitter analysis of the entire clock network starting from the `CLK` pin in the `JITTER_SPICE` directory and runs the simulations:

```
tempus> analyze_jitter -from CLK -level true -out_dir JITTER_SPICE -eiv_file ./eiv.txt -
eiv_power_ground {vdd vss} -run_simulation
```

When the Spice simulations are completed, a summary of the jitter analysis will be saved in the output directory that contains the jitter values of all the endpoints, as shown below:

```
-----
-----
Start-point-> [through-point-> through-point] -> End-point Rise/Fall Cycle-to-Cycle
Jitter Value (ps)
-----
-----
```

```
CLK -> DFF_2/DFF/D (F) 10.782
CLK -> DFF_2/DFF/D (R) 11.072
CLK -> DFF_2/DFF/CP (R) 9.054
CLK -> DFF_2/DFF/CP (F) 9.438
```

- The following command runs jitter analysis for the clock network that originates from the `CLK` node, and traverses through an intermediate node `INV/ZN`:

```
tempus> analyze_jitter -from CLK -through INV/ZN -level true -out_dir JITTER_SPICE -
eiv_file ./eiv.txt -eiv_power_ground {vdd vss} -run_simulation -levels_combine 1 -
max_spectre_lic 8
```

The specified clock network is not simulated as a single netlist, but is broken down into multiple sub-trees. All the leaf nodes driven by a single driver are part of one sub-tree. The simulations on these smaller netlists are scheduled in such a way that a maximum of 8 simulations are run in parallel at any given time.

Related Commands

- `report_jitter`

check_noise

```
check_noise
[-help]
[-all]
[-check_only {receiver_no_propagation_model | receiver_no_dc_tolerance |
driver_no_current_source_model | driver_no_model}]
[-instance_list string]
[-instance_only {true | false}]
[-model_type {receiver | driver}]
[-pins string]
[-unique {true | false}]
[-verbose]
[-view string]
[ [ > | >> ] filename ]
```

Performs several consistency and completeness checks on noise models specified for a design. These checks help to ensure that the right set of models are available for the SI analysis engine to perform cross-talk noise analysis.

The settings from both the [set_glitch_threshold](#) and [set_annotated_glitch](#) commands are taken into account when the `check_noise` command is issued.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-all</code>	Displays all the debug information.
<code>-check_only {receiver_no_propagation_model receiver_no_dc_tolerance driver_no_current_source_model driver_no_model}</code>	
	Checks the warning name. The following warnings are checked: • <code>receiver_no_propagation_model</code>: Shows how many design pins are missing the receiver model for propagation. • <code>receiver_no_dc_tolerance</code>: Shows how many pins have no DC VH/VL tolerance specified. • <code>driver_no_current_source_model</code>: Shows how many design pins are missing the current source model. • <code>driver_no_model</code>: Specifies how many design pins are missing the driver model.
<code>-instance_list</code> <i>string</i>	Specifies the names of the instances.
<code>-instance_only</code> {true false}	Prints each instance only once.
<code>-model_type</code> {receiver driver}	Checks the presence of a valid model type - <code>receiver</code> or <code>driver</code> model. If the specified model is missing, a warning will be issued. The valid receiver models are the models having vivo tables, such as, CDB, CCSN, ECSMN. The valid driver models are CDB, CCS, ECSM, NLDM, and UDN.
<code>-pins</code> <i>string</i>	Specifies the instance pin names.
<code>-unique</code> {true false}	Reports unique cells or pins for each power domain.
<code>-verbose</code>	Generates verbose details.
<code>-view</code> <i>string</i>	Specifies the view name.
<i>filename</i>	Redirects output to a file.
<code>>>filename</code>	Appends to an output file.

Examples

Here are some examples.

- The following command generates the output as shown below:

```
tempus> check_noise -type receiver_model

**WARN: (IMPESI-3125): AAE_WARN: The analysis view specified to check_noise is not found
or specified. Checking view default_emulate_view_setup.

-----

CHECK NOISE SUMMARY

-----

Warning Number of Warning
-----

receiver_no_propagation_model 17931
receiver_no_dc_tolerance 17931

-----

# CHECK NOISE WARNING DESCRIPTIONS:

# receiver_no_propagation_model: The receiver model for glitch
# propagation or ROP is not available, only RIP analysis will be performed.

# receiver_no_dc_tolerance: The input pin do not have vh/vl dc
# tolerance specified in the noise file. Default tolerences will be used.

define_bundled_bus

```
define_bundled_bus  
[-help]  
[-add_members string]  
[-delete_members string]  
[-name string]
```

Allows you to control user-defined bus groups.

The Tempus software automatically identifies bus nets. However, in some cases the software may not be able to mark bus bits properly (or treat marked bits as bus). For improved bus identification, the `define_bundled_bus` command allows you to control the nets that you want to add (or remove) from the list of recognized bus bits.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-add_members <i>string</i></code>	Specifies the name of nets to be added to the group.
<code>-delete_members <i>string</i></code>	Specifies the name of nets to be deleted from the group.
<code>-name <i>string</i></code>	Specifies the name of the group.

Examples

- The following example command will create a bus named bus1 with 3 net members x[1] and x[2]:

```
define_bundled_bus -name bus1 -add_members {x[1] x[2]}
report_bundled_bus -type user_defined
#####
```

Summary:

```
Total number of user defined bus groups reported = 1
Total number of tool inferred bus groups reported = 0
```

Group Name (user_defined) : bus1

Constituents:

```
- x[1]
- x[2]
```

- The following example command will add one more member x[3] and delete member x[2] to the bus 'bus1':

```
define_bundled_bus -name bus1 -add_members x[3] -delete_members x[2]
Added [1] net(s) to group 'bus1'.
Deleted [1] net(s) from user-defined group 'bus1'.
```

Related Commands

- `report_bundled_bus`

define_glitch_holding_resistance

```
define_glitch_holding_resistance  
[-help]  
[-glitch_type {both | vl | vh | vlu | vho | vl_vh | vlu_vho}]  
[-instance_pin string]  
[-lib_pin string]  
-value double  
[-views string]
```

Allows you to specify the holding resistance.

You can use this command to define a net-specific holding resistance instead of using the default holding resistance of 1000 ohms.

This command can be specified more than once per net. If there is a duplicate specification, then the last setting is used.

Parameters

-help	Prints out the command usage.
-glitch_type {both vl vh vlu vho vl_vh vlu_vho}	Specifies the glitch type for resistance Hold application. The option <code>both</code> applies the value to VL and VH.
-instance_pin <i>string</i>	Specifies a list of instance pin names.
-lib_pin <i>string</i>	Specifies the instance/pin name of the driver that the holding resistance should be applied to.
-value <i>double</i>	Specifies the value in ohms of the holding resistance to be used by glitch analysis.
-views <i>string</i>	Specifies a list of view names. If this parameter is not specified, then by default all the views are applied.

Examples

- The following command sets the holding resistance on the Y pin of inst1 to 233ohms for VL:

```
tempus > define_glitch_holding_resistance -glitch_type vl -lib_pin {inst1/Y} 233
```
- The following command sets the holding resistance on the Y pin of inst2 to 380ohms for both VL & VH:

```
tempus > define_glitch_holding_resistance -glitch_type both -lib_pin {inst1/Y} 233
```

define_parameter

```
define_parameter  
[-help]  
[<setup/hold>]  
[-correlation <string>]  
[-distribution <string>]  
[-moments <string>]  
[-name <string>]  
[-range <string>]  
[-related <string>]  
-scope <string>  
[-view <string>]
```

Provides variation information to Tempus. You can directly specify the range information and Tempus will internally calculate moments and use it for wire variation calculation.

Parameters

<code>-help</code>	Prints out the command usage.
<code><setup/hold></code>	Defines parameter that is valid for setup or hold.
<code>-correlation</code> <code><string></code>	Specifies correlation between different parameters of the same scope - parameters need to be pre-defined.
<code>-distribution</code> <code><string></code>	Specifies the parameter distribution. You can also use user-defined distribution.
<code>-moments</code> <code><string></code>	Specifies the parameter moments - mean or std-dev.
<code>-name <string></code>	Specifies the name of the parameter.
<code>-range <string></code>	Specifies the parameter minimum or maximum range - min or max.
<code>-related</code> <code><string></code>	Specifies the related information on sub-scope of parameter within the specified <code>-scope</code>. For back end-of-line (BEOL), the allowed arguments are: • <code><layer name></code>: capacitance • <code><layer name></code>:resistance
<code>-scope <string></code>	Specifies the parameter scope - vtskew, wire_variation, or via_variation.
<code>-view <string></code>	Specifies the view name.

Examples

- The following command defines R/C range for normal distribution for M1 layer for setup for view view1:

```
define_parameter setup -view view1 -name param_M1_R -scope wire_variation -distribution gaussian -range {1 1.15}
define_parameter setup -view view1 -name -param_M1_C -scope wire_variation -distribution gaussian -range {0.95 1}
```
- The following command defines R/C moments for normal distribution for M1 layer for setup for all views:

```
define_parameter setup -name param_M1_R -scope wire_variation -distribution gaussian -moments {0.2 0.01}
define_parameter setup -name param_M1_C -scope wire_variation -distribution gaussian -moments {0.95 1}
```
- The following command defines correlation between metal layers - if M1, M2 and M3 are fully correlating:

```
define_parameter -scope wire_variation -correlation {{param_M1_C param_M2_C param_M3_C} {1.0}}
```

Related Commands

get_glitch_threshold

```
get_glitch_threshold
[-help]
[-cells string]
[-failure_dependency {none | input | last}]
[-failure_point {none | input | internal | last}]
[-glitch_type {both | vl | vh | vlu | vho}]
[-library_pins string]
[-nets string]
[-pin_type {all | clock | data | latch}]
[-pins string]
[-threshold_type {reporting | failure}]
[-views string]
```

Displays information for the specified [set_glitch_threshold](#) parameters for the current Tempus session. If you do not specify a parameter, the software displays information for all [set_glitch_threshold](#) parameters.

Parameters

<i>parameter_names</i>	Displays information for the specified parameter. You can specify one or more parameters. See set_glitch_threshold for descriptions of the timing analysis mode parameters you can specify.
------------------------	---

Examples

- The following command shows the failure threshold for ROP for single stage cells:

```
get_glitch_threshold -failure_point last
```

Here's the command output:

```
value=0.4 -threshold_type reporting -glitch_type both -pin_type all -failure_point last
-failure_dependency none
```
- The following command shows the failure threshold for the ROP for the internal net of multi-stage cells:

```
get_glitch_threshold -failure_point internal
```

Here's the command output:

```
value=0.2 -threshold_type reporting -glitch_type both -pin_type all -failure_point
internal -failure_dependency none
```

- The following command shows the failure threshold for the RIP for the input net of cells without CCSN/ECSMN/cdB

```
get_glitch_threshold -failure_point input
```

Here's the command output:

```
value=0.5 -threshold_type reporting -glitch_type both -pin_type all -failure_point input  
-failure_dependency none
```

Related Commands

get_multi_input_switching_mode

```
get_multi_input_switching_mode  
[-help]  
{[-disable_lib_cells ] [-switching_alignment_factor ] [-mis_alignment_mode]}
```

Reports the MIS (multi-input switching) analysis settings configured using `set_multi_input_switching_mode` command.

Parameters

-help	Prints out the command usage.
-disable_lib_cells <string>	Reports all the user-specified library cells for which multi-input switching (MIS) mode support is disabled.
-mis_alignment_mode {0 1}	Returns the current value set (0 or 1) of the MIS alignment mode.
- switching_alignment_factor <float>	Returns the switching alignment factor specified globally.

Related Commands

- `set_multi_input_switching_mode`
- `report_delay_calculation`
- `report_timing`
- `write_spice_deck`

Related Information

get_via_variation_mode

```
get_via_variation_mode
[-help]
[-corner_sigma_multiplier]
[-correlation_type]
[-reset]
[-separate_params_for_via]
[-quiet]
[-nonDefault]
```

Displays the following information about the specified `set_via_variation_mode` command parameters in the Tempus log file and the Tempus console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify any parameters, the software displays information for all of the parameters.

Parameters

<code>-help</code>	Prints out the command usage.
<i>parameter_names</i>	Displays information for the specified parameters. You can specify one or more parameters. See <code>set_via_variation_mode</code> for descriptions of the parameters you can specify.

Related Commands

- `set_via_variation_mode`

merge_noise_reports

```
merge_noise_reports  
[-help]  
-base_dir <string>  
[-delay {max | min}]  
[-double_switching]  
[-failure]  
[-reverse_voltage_change_threshold <float>]  
[-sort_by {noise | receiver_peak}]  
[-threshold <float>]  
-out_file <string>  
[-views <string>]
```

Generates merged noise reports for the specified views.

Parameters

-help	Prints out the command usage.
-base_dir <string>	Specifies the name of the directory provided as input to the <code>report_noise -merge_dir</code> parameter.
-delay {max min}	Specifies the uncertainty type (maximum or minimum delay).
-double_switching	Enables double switching reporting.
-failure	Shows output glitch report for failure nets only.
-reverse_voltage_change_threshold <float>	Reports the minimum reverse swing threshold values.
-sort_by {noise receiver_peak}	Specifies the sorting of the report based on noise or receiver_peak.
-threshold <float>	Reports the glitch (in mV) or uncertainty (in ps) filter threshold values.
-out_file <string>	Specifies the name of the output file.
-views <string>	Specifies the name of views to include in the merged output.

Related Commands

- `report_noise`

report_bundled_bus

```
report_bundled_bus  
[-help]  
[-name string]  
[-nets string]  
[-type {user_defined | tool_inferred}]  
[[ > | >> ]]
```

Generates a report for bundled buses.

Parameters

-help	Prints out the command usage.
-name <i>string</i>	Specifies the name of the user-defined bus group(s) to be reported.
-nets <i>string</i>	Specifies the name of the net(s) to be reported.
-type {user_defined tool_inferred}	Reports the type of bundled bus(es) - user-defined or tool-inferred - to include in the report. By default, the <code>report_bundled_bus</code> command generates reports for both user-defined and software-inferred type of buses.
> <i>filename</i>	Redirects the output to the specified file.
>> <i>filename</i>	Appends to the specified output file.

Examples

- The following command reports details of user-defined bus group `bus1`:

```
tempus > report_bundled_bus -name bus1  
  
Summary:  
Total number of user defined bus groups reported = 1  
Total number of tool inferred bus groups reported = 0  
  
-----  
  
Group Name (user_defined) : bus1  
  
Constituents:  
- FE_OF_13
```

- The following command reports details of user-defined bus group `bus2` for the specified nets:

```
tempus > report_bundled_bus -nets FE_OF_2
Summary:
Total number of user defined bus groups reported = 1
Total number of tool inferred bus groups reported = 0

-----

Group Name (user_defined) : bus2

Constituents:
- FE_OF_2
```

- The following command reports the `user_defined` bundled buses:

```
tempus > report_bundled_bus -type user_defined

Summary:
Total number of user defined bus groups reported = 2
Total number of tool inferred bus groups reported = 0

-----

Group Name (user_defined) : bus1

Constituents:
- FE_OF_13

-----

Group Name (user_defined) : bus2

Constituents:
- FE_OF_2
- FE_OF3_data_out_1

-----
```

- The following command shows the user-defined bus groups:

```
report_bundled_bus

Summary:
Total number of user defined bus groups reported = 3
Total number of tool inferred bus groups reported = 41

-----

Group Name (user_defined) : grp1

Constituents:
- EJ_PartNumber[15]
- EJ_PartNumber[14]

report_double_clocking

```
report_double_clocking  
[-help]  
[-max_delta_delay float]  
[-max_slew float]  
[-nworst integer]  
[-out_file string]  
[-reverse_slope_limit float]  
[-reverse_voltage_change_threshold float]  
[-view string]
```

Reports noise impact on clock nets by generating information on the double clocking, transition type, and reverse slope.

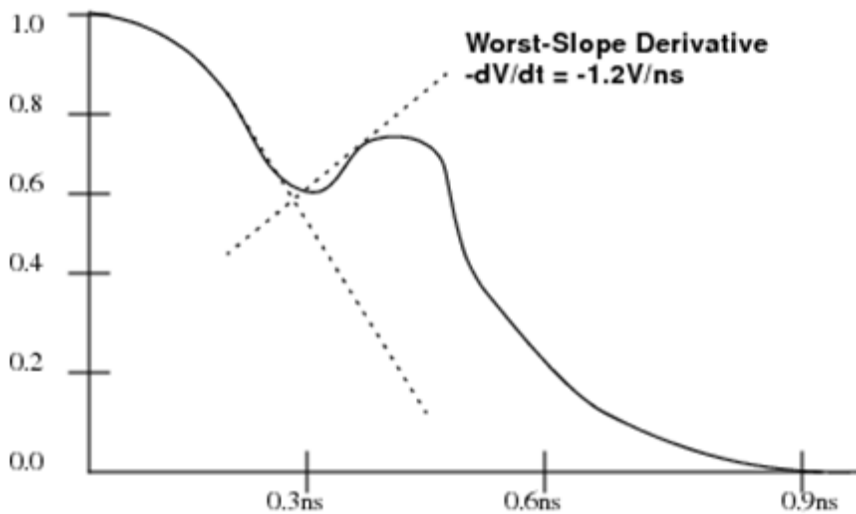

Note: The `report_double_clocking` command requires that clocks have been defined and applied prior to timing analysis with SI (`update_timing` or `report_timing`). The `report_double_clocking` command does not work with the glitch-only flow (`update_glitch`).

Double clocking occurs when the noise glitch attacks a transitioning signal. The multiple transition or double clocking check supplements the transition time check performed in static timing analysis. Transition time is defined as the duration of time that a signal takes to make the transition between two threshold points. However, transition time does not account for the waveform shape between the voltage thresholds.

For special signals such as clocks it is important to analyze the waveform shape between the voltage threshold in case the signal transitions slowly or in the opposite direction (even for a short duration of time) causing multiple clock edges. This command enables you to report the worst-case slope (dV/dt for rising signal and $-dV/dt$ for falling signal) of a signal transitioning between the voltage thresholds. The slope derivative is measured in units of volts per nanosecond (V/ns). This value can be positive if the signal does not change direction, 0 if the signal is flat, and negative if the signal changes direction even for a short duration of time.

The following figure shows two falling signal transitions:

Figure: Negative Worst-Slope Derivative

In the above figure, the falling signal transitions have identical transition times. However, the worst-case slope derivatives for the two falling waveforms are different. If a clock signal exhibits a negative slope derivative as in the case of Figure 13-2, there is a possibility of a double clocking functional failure. A higher reverse slope results in a higher possibility of a double clocking functional failure.

The double clocking report contains the following sections and their corresponding fields:

- **Double Clocking**
 - Rise Slope (V/ns): Specifies the worst reverse slope of the rising clock signal as a measure of volt per nano-second.
 - Fall Slope (V/ns): Specifies the worst reverse slope for the falling clock signal as a measure of volt per nano-second.
 - VictimNet: Specifies the name of the victim net.
- **Transition Type**
- **Reverse Slope**

Parameters

<code>-help</code>	Prints out the command usage.
<code>-out_file <string></code>	Specifies the output filename. <i>Default:</i> <code>{\$parm_filename_prefix}_clock.text</code>

<code>-max_delta_delay float</code>	Reports clock nets, for which the delay change caused due to noise, exceeds the specified number. <i>Default: 0</i>
<code>-max_slew float</code>	Reports clock nets for which the transition time, including SI, exceeds the specified number. <i>Default: 0</i>
<code>-nworst integer</code>	Specifies the number of clock nets to report in each category. <i>Default: 1</i>
<code>-reverse_slope_limit float</code>	Reports the clock nets for which the slope is below the specified number. <i>Default: 0</i>
<code>-reverse_voltage_change_threshold float</code>	Controls the reverse slope failure criteria by allowing you to supply a minimum voltage change as a percentage of VDD. The reverse slope must be sustained in order for it to be considered as failing. <i>Default: 0.1</i>
<code>-view string</code>	Specifies the view name for which the report to be generated.

Examples

- The following command reports clock nets that have a reverse slope less than -1:
`report_double_clocking -reverse_slope_limit -1`
- The following command reports 100 clock net violations of each category:
`report_double_clocking -nworst 100`

Related Commands

report_glitch_thresholds

```
report_glitch_thresholds  
[-help]  
[-failure_point {input | output}]  
[-glitch_type <string>]  
[-instance_pins <string>]  
[-library_pins <string>]  
[-list_unannotated_instance_pins]  
[-list_unannotated_library_pins]  
[-view <string>]
```

Reports user-defined glitch thresholds applied on library or instance pins.

Parameters

-help	Prints out the command usage.
-failure_point {input output}	Specifies if threshold failure point is input or output. <i>Default:</i> input
-glitch_type <string>	You can specify one or more glitch types (space-separated) for reporting. The valid options are: vl, vh, vlu, vho, and all. When the -glitch_type parameter is specified, only the user-specified glitch types will be checked. <i>Default:</i> all
-instance_pins <string>	Specifies a list of instance pin names.
-library_pins <string>	Specifies a list of library pin names to be reported.
-list_unannotated_instance_pins	Reports list un-annotated instance pins. Reports all the instance input pins which do not have glitch threshold applied.
-list_unannotated_library_pins	Shows a list of all the library input pins which are not covered by library pin-based/corresponding library cell-based glitch threshold.
-view <string>	Specifies the view name.

Examples

- The following report shows instance-pin specific glitch threshold summary:

```

+-----+
|                                     |
|           Instance-Pin Glitch Thresholds Summary           |
|                                     |

report_instance_cdb

```
report_instance_cdb  
[-help]  
[-analysis_type {early | late}]  
[{instance_list or collection}]  
[-out_file string]  
[-quiet]  
[-view viewname]
```

Allows you to report the cdB associated with all the instances or a subset of instances in a design.

Note: This command must be issued after [report_timing](#), [update_timing](#), or [update_glitch](#) commands.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>report_instance_cdb</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_instance_cdb</code>
- analysis_type {early late}	Specify the analysis type for the query. <i>Default:</i> late
instance_list or collection	Specify the instance for which the cdB association is desired. By default, the cdB association for all the instances is reported.
-out_file string	Specify the output filename for the instance report to go to. By default, the report output is displayed on the screen.
-quiet	Suppresses warning messages for cells missing in CDB files.
-view {viewnames}	Specifies the view names. By default, values for all the views are reported.

Examples

- The following command reports the cdB instance connection for all the instances in the design and write it to the inst_cdb.rpt file:

```
tempus > report_instance_cdb -output_file inst_cdb.rpt
```

- The following command reports the cdB instance connection for the u5 instance to the screen:

```
tempus > report_instance_cdb u5
```

```
VIEW: default_emulate_view -- ANALYSIS TYPE: late
```

```
u5 : inv_t1 : test1.cdb.txt
```

- The following command reports the cdB instance connection for the early analysis type for the u5 and u6 instances

```
tempus > report_instance_cdb -analysis_type early {u5 u6}
```

```
VIEW: default_emulate_view -- ANALYSIS TYPE: early
```

```
u5 : inv_t1 : test1.cdb.txt
```

```
u6 : inv_t2 : test2.cdb.txt
```

report_jitter

```
report_jitter
[-help]
[-eiv_end_time float]
[-eiv_file string]
[-eiv_power_ground string]
[-eiv_start_time float]
[-from string]
[-from_fall string]
[-from_rise string]
[-mode {period | cycle_to_cycle | time_interval_error}]
[-out_dir string]
[-through <string>]
[-to string]
[ [ > | >> ] ]
```

Provides a native jitter interface to report jitter through the native Tempus engine.

The existing `analyze_jitter` command will continue to be used for Spice-based jitter analysis.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-eiv_end_time float</code>	Specifies the end time in EIV.
<code>-eiv_file string</code>	Specifies the effective instance voltage files for accounting IR Drop in Jitter computation.
<code>-eiv_power_ground string</code>	Specifies the power and ground net name for each EIV file. It is mandatory to provide power and ground net name for each eiv file provided using the <code>-eiv_file</code> parameter. For example, "vdd1 vss1 vdd2 vss2", vdd1 and vss1 are for first and vdd2 and vss2 for second EIV file - specified using the <code>-eiv_file</code> parameter.
<code>-eiv_start_time float</code>	Specifies the start time in EIV.
<code>-from string</code>	Creates the Spice deck with mesh net starting from pin.
<code>-from_fall string</code>	Creates the Spice deck with mesh net starting from falling transition of specified from pin.
<code>-from_rise string</code>	Creates the Spice deck with mesh net starting from rising transition of specified from pin.
<code>-mode {period cycle_to_cycle time_interval_error}</code>	Runs the <code>analyze_jitter</code> analysis natively - period is default jitter type.
<code>-out_dir string</code>	Specifies the output directory for the created Spice.
<code>-through <string></code>	Creates the Spice deck with mesh net going by through points.
<code>-to string</code>	Creates the Spice deck with mesh net ending at to pins.
<code>> filename</code>	Redirects the <code>-run_path_simulation/-run_simulation</code> output to a file.
<code>>> filename</code>	Appends the <code>-run_path_simulation/-run_simulation</code> output to a file.

Examples

- The following command reports analysis jitter details (for `period` mode) in the specified output directory:

```
report_jitter -eiv_file eiv_file1 -out_dir jitter_dir -mode period
```
- The following command reports analysis jitter details (for `cycle_to_cycle` mode) in the specified output directory:

```
report_jitter -eiv_file eiv_file1 -out_dir jitter_dir -mode cycle_to_cycle
```

Related Commands

- `analyze_jitter`

report_mutex_condition

```
report_mutex_condition
[-help]
[-filename <string>]
[-net <string>]
```

Reports mutex nets of a victim net.

When this command is used, all the coupled nets that are participating in mutex for a victim will be reported. The coupled nets will be reported as a group of mutex nets (user-defined). By default, all the mutex conditions are reported.

Parameters

-help	Prints out the command usage.
-filename <string>	Specifies the name of the file that saves the command output results.
-net <string>	Reports the coupled nets mutex to the specified net name. You can specify multiple net names with multiple <code>report_mutex_condition</code> commands.

Examples

- The following example shows mutex nets of a victim net. This report does not indicate the attackers not listed due to mutex command:

```
Vic: Net1
Attackers: Att1, Att2, Att3
set_mutex_condition {Att1, Att2 }
set_mutex_condition {Att2, Att3 }
set_mutex_condition {Att1, Att3 }

report_mutex_condition -net Net1 will report:
```

```
- Victim Net: Net1
Mutex groups:
{Att1, Att2 },
{Att2, Att3 },
{Att1, Att3 }
```

- The following example shows that if a coupled net is having LC chain then the entire chain will be reported along with other mutex group nets:

```
Vic: Net1
Attackers: Att1, Att2, Att3
Att1 chain: Agg1 Agg11 Agg111
Att2 chain: Agg2 Agg22 Agg222
Att3 chain: Agg3 Agg33 Agg333
set_mutex_condition {Att1, Att2 }
set_mutex_condition {Att2, Att3 }
set_mutex_condition {Att1, Att3 }

report_mutex_condition -net Net1 will report:
```

```
- Victim Net: Net1
Mutex groups:
{{ Agg1 Agg11 Agg111 }, { Agg2 Agg22 Agg222}}
{{ Agg2 Agg22 Agg222}, { Agg3 Agg33 Agg333}}
{{ Agg1 Agg11 Agg111 }, { Agg3 Agg33 Agg333}}
```

Related Commands

- [set_mutex_condition](#)

report_noise

```
report_noise
[-help]
[-cell_type string]
[-clock]
[-delay {max | min}]
[-double_clocking]
[-double_switching]
[-exclude_failures]
[-expand_virtual_attacker_bus]
[-failure]
[-format string]
[-gui_victim_nets_file]
[-histogram]
[-level string]
[-max_threshold float]
[-merge]
[-merge_dir string]
[-nets string]
[-noisy_waveform]
[-out_file string]
[-output_format string]
[-overshoot_undershoot]
[-pins string]
[-precision integer]
[-quiet_nets]
[-remove_status_row <string>]
[-report_virtual_attacker_constituents]
[-reverse_voltage_change_threshold <float>]
[-slack float]
[-skip_nets_or_pins_in_header]
[-sort_by string]
[-style {default | detailed}]
[-threshold string]
[-type string]
[-view string]
```

Generates text-based noise reports.

Note: You need to ensure that the `si_glitch_enable_report` (to generate glitch report) or `si_delay_enable_report` (to generate detailed delay report) attributes are set to `true`, before the `report_timing`, `update_timing`, or `update_glitch` commands are run.

For more information on attributes, see [si Category Attributes](#).

Parameters

<code>-help</code>	Prints out the command usage.
<code>-clock</code>	Prints out the signal integrity report for the clock network.
<code>-cell_type <i>string</i></code>	Generates a glitch report for the user-specified cell-type. You can specify one of the following options: • <code>bbox</code>: Generates a report for only the black-box receivers • <code>clock</code>: Generates a report for only the clock pin receivers • <code>data</code>: Generates a report for only the data pin receivers • <code>latch</code>: Generates a report for only the latch pin receivers
<code>-delay {max min}</code>	Reports delay uncertainty instead of noise values. The valid options are <code>min</code>, <code>max</code> - for minimum or maximum path delay analysis. The <code>report_noise -clock -delay min max</code> command outputs minimum/maximum delay report for clock nets. The attacker constituents are reported for nets which are critical and thereby reselected in the second SI iteration. For non-critical nets, the constituent section will be ignored. To report attacker constituents for such nets, the <code>report_delay_calculation -si</code> parameter can be used.
<code>-double_clocking</code>	Enables double clocking reporting.
<code>-double_switching</code>	Reports double switching analysis data in noise reports.
<code>-exclude_failures</code>	Excludes all failing nets from the glitch report.
<code>-expand_virtual_attacker_bus</code>	Reports virtual attacker components and expands bus bits in the noise reports. This parameter works only when the bus virtual attacker feature is enabled using the <code>si_enable_virtual_attacker_constituent_report true</code> setting.

<code>-failure</code>	Reports receiver peak failures and DC tolerance failure nets. Use this option only for glitch noise failure reports. Option: Directory Name: <code>-sort_by noise glitch</code> <code>-sort_by rcvr_peak glitch</code>
<code>-format <i>string</i></code>	Specifies the output report format fields. The valid fields are: arc, attacker_edge, attacker_logical_correlation_phase, attacker_net, attacker_offset, attacker_peak, attacker_slew, attacker_source, attacker_status, attacker_vdd, attacker_wire_length, attacker_xcap, cell_type, delay, glitch_slack, incr_delay, level, peak, receiver_cell, receiver_input_failure_threshold, receiver_input_pin, receiver_output_failure_threshold, receiver_output_peak, slack, slack_status, stage_info, thresh_source, verbose_logical_correlation_report, victim_edge, victim_library, victim_logical_correlation_phase, victim_net, victim_slew, victim_total_area, victim_total_cap, victim_total_cross_cap, victim_vdd, victim_width, victim_wire_length Note: The <code>victim_total_cross_cap</code> option is supported only for SI delay reporting. Each field corresponds to the following columns of the glitch report: • arc: Arc • attacker_edge: Edge • attacker_net: Net • attacker_offset: Offset (ps) • attacker_peak: Peak (mV) • attacker_slew: Slew (ps) • attacker_source: Constituents: Source • attacker_status: Statue • attacker_vdd Vdd (V) • attacker_wire_length • attacker_xcap: Xcap (fF)

- glitch_slack: Slack
- level: Level
- peak: Peak (mV)
- receiver_cell: Receiver cell
- receiver_input_failure_threshold: Receiver Input Threshold
- receiver_input_pin: ReceiverNet
- receiver_output_failure_threshold: Failure threshold
- receiver_output_peak: Receiver output peak Value
- stage_info
- thresh_source: ReceiverThresholdType (Global | User | Library)
- victim_library: Library
- victim_net: VictimNet
- victim_total_area: TotalArea
- victim_total_cap: TotalCap (fF)
- victim_vdd: Vdd (V)
- victim_width: Width (ps)
- victim_wire_length

The following options are not available with the single line format:

- delay
- incr_delay
- slack
- thresh_source
- victim_edge
- victim_slew
- victim_total_cross_cap

To choose whether the report format should be on a single line or multiple lines, you can use the `output_format` parameter.

<code>-gui_victim_nets_file</code>	Generates the GUI format glitch reports (<code>aae</code> or <code>aae_<viewname></code> files under the reporting directory) and incremental delay reports (<code>aae_<max/min>_incDelay</code> or <code>aae_<viewname>_<max/min>_incDelay</code> files under the reporting directory) to be used in the Display Noise Net form.
<code>-histogram</code>	Generates the noise histogram.
<code>-level {vl vh vlu vho}</code>	Specifies the level for which a report needs to be generated when single-level report is desired. You can specify one of these options - vl, vh, vlu, and vho.
<code>-max_threshold float</code>	Specifies the maximum peak noise or receiver peak thresholds to report on.
<code>-merge</code>	Generates a merged report that shows only the worst glitch slack for each pin level combination across views.
<code>-merge_dir string</code>	Specifies the name of the merge database.
<code>-nets string</code>	Reports the specified nets in the noise report.
<code>-noisy_waveform</code>	Flags nets with bumpy waveforms at the receiver output.
<code>-out_file string</code>	Specifies the name of the output file name prefix. The name of the output file is generated by combining the prefix and the specified view name. If you do not specify this option: • The software automatically names the text report as 'glitch' for noise glitch reports and 'delay' for noise delay reports. • The software dumps the generated report to the console window for better usability. Note: If the text report file with the <code>.gz</code> extension is used, the output file is zipped to generate a compressed report.

<code>-output_format string</code>	Specifies if the output format should be on a single line or on multiple lines. You can specify one of the following options: • <code>single_line</code> • <code>multiple_line</code> If the <code>single_line</code> option is specified and the attacker info is chosen as a field, then all the attacker related format options will be printed together. The <code>-output_format</code> parameter only works with the <code>-format</code> option and does not affect the default reporting output format. <i>Default:</i> <code>multiple_line</code>
<code>-overshoot_undershoot</code>	Reports the overshoot (VHO) and undershoot (VLU) glitches. <i>Default:</i> If this option is not used during glitch reporting, then VL and VH type of glitches will be reported.
<code>-pins string</code>	Specifies the name of pins to be reported.
<code>-precision integer</code>	Specifies the precision value up to which the glitch data is to be printed. The allowed values are 0, 1, 2 and 3. <i>Default:</i> 2
<code>-quiet_nets</code>	Generates the quiet attackers report.
<code>-remove_status_row <string></code>	Shows only the active attackers and filters out Sb, UF, and LC from the glitch report.
<code>-report_virtual_attacker_constituents</code>	Generates reports for virtual attacker constituents.
<code>-reverse_voltage_change_threshold <float></code>	Reports the clock nets with reverse swing greater than the user-specified threshold value (ratio of VDD). By default, the threshold value is set to 0.1.
<code>-slack float</code>	Generates a report for bumpy nets based on slack. <i>Units:</i> Seconds
<code>-skip_nets_or_pins_in_header</code>	Generates the glitch report without a list of nets or pins in the report header.

<code>-sort_by string</code>	Requests the sorting of entries. You can sort by: • <code>noise</code> • <code>receiver_peak</code> • <code>slack</code> • <code>cell_type</code> Tempus determines the default HTML output directories based on the options you choose. Depending on the sorting option you select, Tempus sorts the report fields in the following order: -sort_by Option Level 1 Level 2 Level 3 Level 4 rcvr_peak receiver peak noise netname level noise noise - netname level
	For example, if you use the <code>-sort_by noise</code> option, the first level of sorting will be based on noise, followed by receiver peak, netname, and level. Note: The report displays the <code>v1</code> noise level before the <code>vh</code> noise level. <i>Default:</i> <code>receiver_peak</code>
<code>-style {default detailed}</code>	Generates reports in one of the two styles - <code>extended</code> and <code>default</code>. • <code>detailed</code>: Generates detailed reports with victim and aggressor timing windows, dropped aggressor slews, and reasons for dropped aggressors. Additionally, the report also shows driver pins and driver library pins. • <code>default</code>: Generates the default report, which is similar to the text report generated using the <code>-text</code> parameter.

<code>-threshold string</code>	Specifies the minimum peak noise, sensitivity, absolute delay uncertainty, relative delay uncertainty, and receiver peak thresholds to report on. <i>Default:</i> • 0.10 of vdd for nets - when the glitch report is generated using the <code>report_noise -sort_by noise</code> option. • 10 (ps) for nets - when a detailed delay report is generated using the <code>report_noise -delay</code> parameter). Note: • The <code>-threshold</code> parameter accepts percentage values. • All <code>-sort_by</code> values that represent voltages will be in mV.
<code>-type string</code>	Specifies the type of noise to be reported - glitch, delay or slew.
<code>-view string</code>	Specifies the view name.

File and Directory Naming Convention for Reports

The software uses a set of naming conventions for the report files and directories that are generated by the `report_noise` command. Each type of report file or directory is identified by a combination of strings that are attached to its name. The software adds the appropriate string to the report file or directory name.

Noise Reports

For noise reports, the `report_noise` command uses the following naming convention for report files or directories:

glitch

Delay Reports

For delay reports, the `report_noise` command uses the following naming convention for report files or directories:

delay

Report File or Directory Name Examples

This section contains examples of using the `report_noise` command with different options to generate different types of reports and depicts the corresponding impact on the name of the report file or directory.

Examples of Generating Noise Report Files or Directories

The following table shows the combination of different options used with the `report_noise` command for noise reports and the corresponding names of the generated report files or directories:

Command(s)	Report File/Directory Name
<code>report_noise -sort_by noise -out_file example_glitch.txt</code>	<code>example_glitch.txt</code>
<code>report_noise -sort_by rcvr_peak -out_file example_recevier_peak.txt</code>	<code>example_receiver_peak.txt</code>
<code>report_noise -failure -out_file failure.txt</code>	<code>failure.txt</code>

Examples of Generating Delay Report Files or Directories

The following table shows the combination of different options used with the `report_noise` command for delay reports and the corresponding names of the generated report files or directories:

Command(s)	Report File/Directory Names
<code>report_noise -delay min -out_file min_delay.txt</code>	<code>min_delay.txt</code>
<code>report_noise -delay max -out_file max_delay.txt</code>	<code>max_delay.txt</code>

Sample Delay Report

```
Type IncrementalDelay(ps) Delay(NomMax/Max) VictimNet
R      1725.800           128.300/1854.100  inst1/I {victim}
```

Constituents:

	Offset(ps)	Slew(ps)	Xcap(fF)	Edge	Net
Cp1:	3707.803	3592.375	48.692	F	att1
Cp1:	1028.237	967.125	6.592	F	att2
Cp1:	1055.632	963.625	4.348	F	att3
Cp1:	885.057	744.750	4.330	F	att4

Examples

- The following command prints out a signal integrity report for the clock network:

```
tempus > report_noise -clock -out_file noise.txt
```

Report Options:

```
-----
-type glitch
-clock
-threshold 10 % (of vdd)
[-style default]
[-sortBy noise]
Level      : VH and VL
-----
```

	Input		Internal		Last	
	VL	VH	VL	VH	VL	VH
Clock	0.400	0.400	0.050	0.050	0.050	0.050
Data	0.400	0.400	0.300	0.300	0.150	0.150
Latch	0.400	0.400	0.100	0.100	0.100	0.100

- The following command generates a glitch report for black-box receivers:

```
tempus > report_noise -cell_type bbox -out_file clock1.txt
```

Report Options:

```
-----
-type glitch
-cell_type { bbox}
-threshold 10 % (of vdd)
[-style default]
[-sortBy noise]
Level      : VH and VL
-----
```

	Input		Internal		Last	
	VL	VH	VL	VH	VL	VH

```
Clock      0.400      0.400      0.050      0.050      0.050      0.050
```

```
-----
Data       0.400      0.400      0.300      0.300      0.150      0.150
```

```
-----
Latch     0.400      0.400      0.100      0.100      0.100      0.100
```

```
-----
Glitch Violations Summary :
```

```
-----
Number of DC tolerance violations (VH + VL) = 50
```

```
Number of Receiver Output Peak violations (VH + VL) = 0
```

```
Number of total problem noise nets = 4
```

- The following command reports maximum path delay analysis delay details at the specified threshold:

```
tempus > report_noise -delay max -threshold 1600 -out_file delay_max_format.rpt \
        -format {attacker_slew attacker_xcap attacker_status attacker_edge \
        attacker_net stage_info slack victim_slew victim_total_cross_cap victim_net }
```

Report Options:

```
-----
-type delay
-threshold 1600 (ps)
-delay max
[-style default]
[-sortBy IncrDelay]
-----
```

```

- The following command shows glitch values greater than 0.20 VDD as:

```
tempus > report_noise -threshold 0.20
Output report file name prefix is (null)
Info: Processing report for view default_emulate_view ...
#####
# Command: report_noise -threshold 0.20
# View: default_emulate_view
#####
```

Report Options:

```
-----
-type glitch
-threshold 20% (of vdd)
```

- To generate a glitch report, you can use the following command:

```
tempus > report_noise -txtfile glitch.txt
```

- To generate a glitch report sorted by input noise, you can use the following command:

```
tempus > report_noise -txtfile sort_by_glitch_input.txt -sort_by noise
```

- To generate a glitch failure report, you can use the following command:

```
tempus > report_noise -txtfile glitch_failure.txt -failure
```

- To generate a glitch report for VL noises sorted by input noise, you can use the following command:

```
tempus > report_noise -sort_by noise -level vl
```

- To generate a glitch report for only latch receiver pin cell types, you can use the following command:

```
tempus > report_noise -txtfile latch_glitch.txt -cell_type latch
```

For more information on glitch reporting, refer to "[SI Glitch Reporting](#)" in the *Tempus User Guide*.

Related Commands

report_noise_lib_pin

```
report_noise_lib_pin  
[-help]  
[> filename]
```

Generates a report providing information on all the user-specified noise mappings in the design.

Parameters

-help	Prints out the command usage.
> filename	Writes the report to the specified file name. If the file already exists, the software will overwrite it.

Examples

- The following command specifies the library pin name whose definition will be mapped from the given pin name to the given pin name:

```
tempus > set_noise_lib_pin -from PK45_lib_v1.0/A2_X1/B1 -to PK45_lib_v1.0/A2_X1/B2
```

The following command generates a report as follows as per the above definition:

```
tempus > report_noise_lib_pin  
  
-----  
from_pin                                to_pin  
-----  
PK45_lib_v1.0/A2_X1/B1      PK45_lib_v1.0/A2_X1/B2
```

- The following command generates the output report 'noise_mapping.rpt' which contains all the noise mappings present in the design:

```
tempus> report_noise_lib_pin > noise_mapping.rpt  
  
noise_mapping.rpt  
  
-----  
from_pin                                to_pin  
-----

- `reset_noise_lib_pin`

report_noise_propagation

```
report_noise_propagation  
[-help]  
[-level {vl | vh | worst | all}]  
[-max_paths integer]  
[-max_slack float]  
[-nets string]  
[-nworst integer]  
[-pins string]  
[-source_depth integer]  
[-style {default | extended}]  
[-views string]  
[[ > | >> ]]
```

Generates text-based noise propagation reports.

Note: You need to set `si_glitch_enable_report` attribute to `true` to enable glitch reporting.

Parameters

<code>-help</code>	Prints out the command usage. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man report_noise_propagation</code>
<code>-level {vl vh worst all}</code>	Reports the paths for specified glitch level. The allowed values are: VL, VH, worst, or all.
<code>-max_paths integer</code>	Reports the specified number of paths.
<code>-max_slack float</code>	Reports the paths with glitch slack equal to or lesser than the specified value.
<code>-nets string</code>	Reports the paths with end point being all the input pins connected to the net.
<code>-nworst integer</code>	Specifies the maximum number of sources per end point for which paths need to be reported.
<code>-pins string</code>	Reports the paths for the specified end point pins.
<code>-source_depth integer</code>	Specifies the maximum number of sources to be traced in any given branch in the fanin cone of violation.
<code>-style {default extended}</code>	Provides an enhanced report format that shows fields - UDN and User annotated. You can specify the following options: <code>default</code>: Prints the ROP column and VDD (in mV) in the output report. <code>extended</code>: Reports the drivers with annotated glitches as propagation sources.
<code>-views string</code>	Reports the paths for the specified views.
<code>> filename</code>	Redirects output to the specified file.
<code>>> filename</code>	Appends output to the specified output file.

Examples

- The following command reports Reports the maximum number of paths for glitch level VH for the specified views:

```
tempus > report_noise_propagation -level VH -max_paths 2 -views func_fast_RCMAX
```

```
Path 1: VIOLATED RIP failure criteria
```

Endpoint: PLLCLK_INST/refclk (VH)

Source: PLLCLK_INST/refclk (VH)

Analysis View: func_fast_RCMAX

RIP Threshold 792.00

Related Commands

- `report_noise`

report_parameter

```
report_parameter  
[-help]  
[-correlation]  
[-name <string>]
```

Generates a report showing `define_parameter` command settings.

Parameters

-help	Prints out the command usage.
-correlation	Reports the parameter correlation.
-name <string>	Reports the parameter name.
-scope {vtskew wire_variation beol lle layout_effect}	Reports the parameter scope. Allowed options are: • vtskew • wire_variation • beol • lle layout_effect
-view <string>	Shows the name of the specified view name.

Examples

- The following command reports moments information of M2 layer resistance:

```
tempus > define_parameter -name param_M2_R -scope wire_variation -distribution gaussian  
-range {1, 1.15}  
tempus > report_parameter -scope wire_variation -view func_spg_m4c_cmax
```

```

report_voltage_scaling

```
report_voltage_scaling  
[-help]  
objectListOrCollection  
[-analysis_type {early | late}]  
[-view string]  
[-out_file string]
```

Reports instances whose timing data is interpolated due to voltage mismatch. When a cell is operating in the design at a voltage different from voltages at which it is characterized in the timing libraries, delay calculation (DC) interpolates/derives the timing data at the operating voltage.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-analysis_type {early late}</code>	Specifies whether early or late views have to be checked for voltage scaling. If unspecified, only 'late' views are checked.
<code>-out_file string</code>	Specifies the name of the output file to which the report will be written. When the specified file name contains a directory path, the directory hierarchy is automatically created, if not present. If this option is not specified, the report is written to standard output (screen).
<code>objectListOrCollection</code>	Specifies the name(s) or a collection of leaf-level instance(s) for which voltage scaling needs to be checked and reported. If not specified, all instances of the design are checked.
<code>-view string</code>	Specify the name(s) of view(s) to be checked for voltage scaling. If unspecified, all active analysis views are checked.

Examples

- The following example shows a sample `report_voltage_scaling` report:

```
tempus 2 > report_voltage_scaling i_6 -analysis_type late -view func_worst_cmax  
  
VIEW: func_worst_cmax -- ANALYSIS TYPE: late  
<pin-name> : <cell-name> : <actual-voltage> : <low-lib-name> : <high-lib-name>  
i_6/Y      : BUF5MTH      : 0.820                : elc_08v          : elc_09v
```

The report is generated with the `func_worst_cmax` view. You can use the `-view` parameter to report for other views. You can run the `report_analysis_views` command to list views.

Related Commands

- `report_analysis_views`

report_voltage_swing

```
report_voltage_swing  
[-help]  
-high_threshold float  
-low_threshold float  
[-out_file string]  
[-required_width {all | clock}]  
[-view string]
```

Reports the voltage swings that are shorter than the user-specified thresholds for both clock and data signals.

Parameters

-help	Outputs a brief description of the <code>report_voltage_swing</code> command. For a detailed description of the command, use the <code>man</code> command: <code>man report_voltage_swing</code>
-high_threshold <i>float</i>	Specifies the high threshold percentage of the pin supply voltage.
-low_threshold <i>float</i>	Specifies the low threshold percentage of the pin supply voltage.
-out_file <i>string</i>	Specifies the name of the output file.
-required_width {all clock}	Reports the required high and low pulse widths corresponding to the user-specified high and low thresholds. You can specify one of the following options: • <code>clock</code>: Reports the required widths for all clock pins in the design. • <code>all</code>: Reports the required pulse widths for all input pins in the design. <i>Default:</i> <code>all</code>
-view <i>string</i>	Specifies the name of the view being defined. Note: If this option is not specified, it will dump report for all views.

Examples

- The following command shows the total number of voltage swing violations at the specified high and low thresholds:

```
report_voltage_swing -high_threshold 0.6 -low_threshold 0.1
```

```
Total number of voltage swing (Rail to Rail) violations : 505
```

```
Total number of voltage swing (Rail to Rail) violations : 453
```

```
Total number of voltage swing (Rail to Rail) violations : 142
```

```
Total number of voltage swing (Rail to Rail) violations : 142
```

- The following command shows the total number of voltage swing violations for the view, `func_slow_RCMAX`, at the specified high and low thresholds:

```
report_voltage_swing -high_threshold 0.6 -low_threshold 0.1 -view func_slow_RCMAX
```

```
Total number of voltage swing (Rail to Rail) violations : 505
```

- The following command reports the required pulse widths for all input pins in the design corresponding to the specified high and low thresholds in the `rep` output file:

```
report_voltage_swing -high_threshold 1 -low_threshold 0.9 -required_width all -out_file rep
```

reset_glitch_derate

```
reset_glitch_derate  
[-help]  
[-derate_height]  
[-derate_width]  
[-glitch_type string]  
[-instance_pin string]  
[-offset]  
[-pin string]  
[-view string]
```

Removes the derating factors for glitch waveforms that were previously set using the `set_glitch_derate` command.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-derate_height</code>	Resets the derate height.
<code>-derate_width</code>	Resets the derate width.
<code>-glitch_type <i>string</i></code>	Specifies the glitch type vl, vh, or both.
<code>-instance_pin <i>string</i></code>	Specifies the instance pin names on which derate factors are to be reset.
<code>-offset</code>	Resets the derate offset.
<code>-pin <i>string</i></code>	Specifies the library pin names on which derate factors are to be reset.
<code>-view <i>string</i></code>	Specifies the view name.

Related Commands

- `set_glitch_derate`

reset_noise_lib_pin

```
reset_noise_lib_pin  
[-help]  
[-all]  
[-to string]
```

Allows you to reset any noise property mapping, specified previously using the `set_noise_lib_pin` command.

Parameters

-help	Prints out the command usage.
-all	Resets all the noise mappings in the design.
-to <i>string</i>	Specifies the library pin name for which the user-specified noise mapping (if any) needs to be reset. Note: The <code>-to</code> parameter accepts library cell pin names (that can be obtained using the <code>get_lib_pins</code> command). This parameters does not honour collections or instance pin names.

Examples

- The following command resets any noise mapping previously applied to the library pin `library1/macro_cell/A` :

```
tempus> reset_noise_lib_pin -to library1/macro_cell/A
```

- The following command resets all the existing noise mappings in the design:

```
tempus> reset_noise_lib_pin -all
```

Related Commands

- `set_noise_lib_pin`
- `report_noise_lib_pin`

set_advanced_variation_mode

```
set_advanced_variation_mode
[-help]
[-disable_arcs <string>]
-scope {vtskew | aging | wire_variation | beol | lle | layout_effect | lde}
```

Sets the advanced variation scope to configure generic effect specific settings.

Parameters

-help	Prints out the command usage.
-disable_arcs <string>	Disables the generic effect for any arc types, such as, constraint:all, constraint:setup, constraint:hold.
-scope {vtskew aging wire_variation beol lle layout_effect lde}	Provides variation specific settings.

Related Commands

- [set_vt_skew_derate](#)

set_annotated_glitch

```
set_annotated_glitch  
[-help]  
[-overshoot string]  
[-ports string]  
[-undershoot string]  
[-view string]  
[-voltage_high string]  
[-voltage_low string]
```

Allows the ability to annotate glitches at any specified pin/port. This command setting will override the VH/VL glitch with the specified value on the given point and use that glitch value to propagate downstream.

If the defined annotated glitch waveforms do not start and end at 0, then the software will not consider those waveforms and a warning will be issued. In the following example both VL and VH waves should start and end with 0.0 values. Since the VH wave is not ending at 0, this waveform will be ignored.

```
set_annotated_glitch -voltage_low {0 0 100e-12 0.01 200e-12 0.04 300e-12 0.03 600e-12 0} -  
ports dff1/CK -voltage_high {0 0 100e-12 0.1 200e-12 0.4 300e-12 0.3 600e-12 0.1} .
```

The software does not save (and report) waveforms below 5% of VDD. Consider for example, the annotated glitch defined on a pin as:

```
set_annotated_glitch -ports dff1/CK -voltage_high {0 0 100e-12 0.01 200e-12 0.04 300e-12 0.03  
600e-12 0}
```

In this case, the glitch peak is 0.04 (40mV), which is below 5% of VDD (1080mV) - equal to 54mV. Since this annotated glitch waveform peak is very low, the `report_noise` command will not report it. However, if the failure criteria is lower than 5%, then the software will save and report small glitch violations.

Parameters

-help	Prints out the command usage.
-ports <i>string</i>	Specifies port or pin names on which you need to apply glitches. This parameter works only when <code>si_enable_glitch_propagation</code> attribute is set to true in the <code>report_timing/update_timing</code> flow. In the <code>update_glitch</code> flow, the <code>si_enable_glitch_propagation</code> attribute is already set to true.
-overshoot <i>string</i>	Specifies a list of VHO glitch wave points.
-undershoot <i>string</i>	Specifies a list of VLU glitch wave points.
-view <i>string</i>	Specifies a list of view names.
- voltage_high <i>string</i>	Specifies a list of VH glitch wave points. You must specify at least 3 time value pairs.
-voltage_low <i>string</i>	Specifies a list of VL glitch wave points. You must specify at least 3 time value pairs.

Examples

- The following example annotates the specified VL glitch wave points:
tempus > set_annotated_glitch -voltage_low {0 0.0 0.2e-9 0.540 0.405e-9 0} -
voltage_high {0.1e-9 0 0.205e-9 0.50 0.405e-9 0.200 0.6e-9 0.0} -ports {A}
- The following command overrides the glitch value at RIP with the annotated glitch, because glitch is annotated at the receiver input:

```
tempus > set_annotated_glitch -voltage_low {0 0 100e-12 0.1 200e-12 0.4 300e-12 0.3
600e-12 0} -ports seg2/u9/D
tempus > update_glitch
tempus > report_noise -nets seg2/n8
```

```
-----
Peak(mV) Level TotalCap(fF) TotalArea Width(ps) Vdd(mV) Library VictimNet

set_cdb_binding

```
set_cdb_binding  
[-help]  
-from string  
-to string
```

Provides an overriding mechanism that allows overriding a UDN to Liberty mapping at the Tempus command file level.

This command helps to correct any mismapped cases by enabling the software to select a user-specified cdb to Liberty mapping.

Parameters

-help	Prints out the command usage.
-from <i>string</i>	Specifies the name of the CDB file and the cell name.
-to <i>string</i>	Specifies the name of the library file.

Examples

- When loading multiple cdb's with the same PVT, but different secondary voltages, you can use the `set_cdb_binding` command to ensure that they get bound correctly, as shown below:

```
set_cdb_binding -from pvt1_1.cdb -to pvt1_1.lib  
set_cdb_binding -from pvt1_2.cdb -to pvt1_2.lib
```

set_glitch_derate

```
set_glitch_derate  
[-help]  
[-derate_height float]  
[-derate_width float]  
[-glitch_type string]  
[-instance_pin string]  
[-offset float]  
[-pin string]  
[-view string]
```

Sets the derating factors for glitch waveforms and determines the effect of on-chip variation on noise.

Parameters

-help	Prints out the command usage.
-derate_height <i>float</i>	Specifies the derate height value. This parameter scales all the glitch waveforms on the specified pins. A value of 1.0 indicates that no glitch waveform derating will take place. A value greater than 1.0, such as 1.1, indicates a 10 percent increase in the magnitude of the complete glitch waveform, which results in an increase in propagated noise and noise failure. A value less than 1.0 reduces the magnitude of the complete glitch waveform.
-derate_width <i>float</i>	Specifies the derate width value.
-glitch_type <i>string</i>	Specifies the glitch type - vl, vh, or all.
-instance_pin <i>string</i>	Specifies the instance pin names on which derate is to be applied.
-offset <i>float</i>	Specifies the derate offset value.
-pin <i>string</i>	Specifies the library pin names on which derate value is to be applied.
-view <i>string</i>	Specifies the name of the view.

Related Commands

- `reset_glitch_derate`
- `update_glitch`

set_glitch_threshold

```
set_glitch_threshold
[-help]
[-cells string]
[-failure_dependency {none | input | last}]
[-failure_point {none | input | internal | last}]
[-glitch_type {both | vl | vh | vlu | vho | vl_vh | vlu_vho }]
[-library_pins <string>]
[-nets string]
[-pins string]
[-pin_type {all | clock | data | latch}]
[-threshold_type {reporting | failure | propagation}]
-value float
[-views string]
```

Allows for additional control of failure criteria for SI glitch analysis.

Parameters

-help	Prints out the command usage. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man set_glitch_threshold</code> .
-cells <i>string</i>	Specifies list of library cell names.
-failure_dependency {none input last}	Specifies the failure dependency. <i>Default:</i> none
-failure_point {none input internal last}	Specifies where the failure or reporting criteria applies. - none: Criteria does not apply. - input: Threshold applies when the failure point is at the input pin of the receiver cell. - internal: Threshold is applied when the failure point is internal to the cell. This occurs for multi-stage cells. The failure point will be the output of the first stage inside the cell. - last: Threshold is applied when the failure point is the output of the cell. This occurs for single-stage cells, such as, inverters. <i>Default:</i> internal and last

<code>-glitch_type {both vl vh vlu vho vl_vh vlu_vho}</code>	Specifies the glitch type the command applies to. • <code>both</code>: Refers to <code>vl</code> and <code>vh</code> type of glitches. • <code>vl_vh</code>: Includes VL and VH noise. • <code>vlu_vho</code>: Includes VLU and VHO noise. <i>Default:</i> <code>both</code>
<code>-library_pins string</code>	Specifies a list of library pin names.
<code>-nets string</code>	Specifies the list of nets the command applies to. Default is not net-specific.
<code>-pins string</code>	Specifies the list of pins the command applies to. The default is not pin-specific.
<code>-pin_type {clock data latch all}</code>	Specifies the pin type the command applies to. <i>Default:</i> <code>all</code>
<code>-threshold_type {failure reporting propagation}</code>	Specifies whether the command options apply to failure, reporting, or propagation criteria. In case of VL/VH glitch analysis, it is mandatory to specify the <code>-threshold_type</code> parameter. This is because when the computed glitch (ROP) at any given stage exceeds the failure threshold (when glitch propagation is enabled), then it is not propagated and is flagged as failure in the noise report. With the <code>-threshold_type failure</code> setting, the propagation will stop as per the new threshold, and the failure flagging will change accordingly. However, with the <code>-threshold_type reporting</code> setting, the propagation threshold remains unchanged, but the failure reporting is updated. When <code>-threshold_type propagation</code> is used, the software allows for failing nets with ROP values less than the propagation threshold to propagate through single stage cells. In case of VLU/VHO glitch analysis, it is optional to use the <code>-threshold_type</code> parameter because the above flow is not applicable. <i>Default:</i> <code>failure</code>
<code>-value float</code>	Specifies the value for the threshold as a ratio of the local VDD. <i>Default:</i> <code>0.1</code>
<code>-views string</code>	Specifies a list of view names.

Examples

- The following command moves the failure point from ROP to RIP for `inst1/a1` and uses a RIP failure of $0.2 \times \text{ReceiverVDD}$:

```
set_glitch_threshold -failure_point input -pin inst1/a1 -threshold_type failure -value 0.2
```
- The following command sets clock failure criteria to $0.1 \times \text{VDD}$, latch failure criteria to $0.2 \times \text{VDD}$ and all other nets to $0.3 \times \text{VDD}$ (set before `update_glitch`):

```
tempus> set_glitch_threshold -threshold_type failure -pin_type all -failure_point last -value 0.3  
tempus> set_glitch_threshold -threshold_type failure -pin_type clock -failure_point last -value 0.2  
tempus> set_glitch_threshold -threshold_type failure -pin_type latch -failure_point last -value 0.1
```
- The following command sets the failure threshold at the output of the 1st channel connect inside all the instances of `macro1` to be 0.2 (set before `update_glitch`):

```
tempus> set_glitch_threshold -threshold_type failure -cell {macro1} -failure_point internal -value 0.2
```
- The following command changes the reporting criteria for latches to be $0.15 \times \text{VDD}$ (set after `update_glitch`):

```
tempus> set_glitch_threshold -threshold_type reporting -pin_type latch -value 0.15
```

If you need to set all the data failure criteria to be 0.3, then you need to make the following settings:

```
tempus> set_glitch_threshold -failure_point internal \  
-threshold_type failure -value 0.3 \  
-pin_type data  
  
tempus> set_glitch_threshold -failure_point last \  
-threshold_type failure -value 0.3 \  
-pin_type data
```

Related Commands

- `update_glitch`

set_model_priority

```
set_model_priority  
[-help]  
[-objects string]  
[-priority_list string]
```

Allows you to define the priority order of models.

Parameters

-help	Prints out the command usage
-objects <i>string</i>	Specifies a list of library cells or library pins for which priority is specified.
-priority_list <i>string</i>	Specifies a list of pin model priority. Default: {ecsm ccs nldm cdb udn}

Examples

- To force CCSN to be used, you can set `timing_library_read_ccs_noise_data` attribute to `true` before reading the timing libraries and then use the following command before using the `update_glitch` command:

```
set_model_priority -priority_list ccs
```

Related Commands

- `update_glitch`

set_mutex_condition

```
set_mutex_condition  
[-help]  
[netNames]
```

Allows the software to use one of the specified attackers - each attacker is evaluated and the worst one (for each victim net) is selected.

This command applies a mutex group to a set of attackers (for a victim) to reduce pessimism. A mutex group is a group of nets of which only one can transition in a given cycle.

Parameters

<code>-help</code>	Prints out the command usage.
<code>netNames</code>	Specifies the net names of the mutex group.

Examples

- The following example shows that only one of the specified nets, between abc[0-3], can switch at any given point of time:

```
tempus> set_mutex_condition {abc[0] abc[1] abc[2] abc[3]}
```

Each of the specified attackers will be evaluated and the worst one will be used.

Related Commands

- `report_mutex_condition`

set_noise_lib_pin

```
set_noise_lib_pin  
[-help]  
-from string  
-to string
```

Allows you to map noise properties of an instance pin to that of different library cell pin.

Parameters

-help	Prints out the command usage.
-from <i>string</i>	Specifies the library pin name whose definition will be mapped from the given pin name.
-to <i>string</i>	Specifies the library pin name whose definition will be mapped to the given pin name. When multiple <code>set_noise_lib_pin</code> commands are run on the same <code>-to</code> pin, the software will honor the first command only. Note: The <code>-from</code> and <code>-to</code> parameters also accept library cell pin names (that can be retrieved using the <code>get_lib_pins</code> command). These parameters do not honor collections or instance pin names.

Examples

- The input pin A of the `macro_cell` cell inherits the noise characteristics of the input pin I of the library cell, `ccs_noise_lib/inv`. This information is used to calculate the noise immunity of the pin, `library1/macro_cell/A`.

```
tempus> set_noise_lib_pin -to library1/macro_cell/A -from ccs_noise_lib/inv/I
```
- The following syntax specifies the library pin name whose definition will be mapped from the given pin name to the given pin name:

```
tempus> set_noise_lib_pin -from [from_lib/from_cell/from_pin] -to  
[to_lib/to_cell/to_pin]
```
- The following syntax specifies that a bidi pin is mapped to two from pins; that is, – 1 input pin and 1 output pin.

```
tempus> set_noise_lib_pin -to library1/macro_cell/PAD -from "ccs_noise_lib/inv/I  
ccs_noise_lib/inv/Z"
```

Related Commands

- `report_noise`

set_outbound_report

```
set_outbound_report  
[-help]  
-delay {early | late | both}  
[-out_file_prefix string]  
[-report_constant_nets {true | false}]  
[-type {lower | upper | both}]
```

Controls what extrapolation information is to be saved in the log file(s). The slew extrapolation information can be stored into separate files.

Parameters

-help	Prints out the command usage
-delay {early late both}	Control whether extrapolation information is to be shown for min or max (or both) analyses. <i>Default:</i> both
-out_file_prefix <i>string</i>	Specify the prefix to be used in the name(s) of the report file(s). <i>Default:</i> design-name
-report_constant_nets {true false}	Controls whether extrapolation information is to be shown for constant nets or not.
-type {lower upper both}	Controls whether extrapolation information is to be shown for lower or upper (or both) outbound slews.

Examples

The following command will will dump slew extrapolation information for maximum analysis into the myreport.dc.outbound.slew.late.<view-name>.txt file:

```
> set_outbound_report -delay late -out_file_prefix myreport
```

set_quiet_aggressor

```
set_quiet_aggressor  
[-help]  
[-analysis_type {early | late}]  
[-aggressor string]  
[-transition {rise | fall}]  
[-victim string]  
[-view string]
```

Specifies one or more coupled nets as non-attackers (silent) for the delay and glitch analysis of a given victim net.

You can run the `update_glitch` or `update_timing` command and view the results in the `report_noise` or `report_timing` command output.

Parameters

-help	Prints out the command usage.
- analysis_type {early late}	Specifies the analysis type for which the attackers will be assumed quiet. If no value is specified, attackers are skipped for both <code>early</code> / <code>late</code> analysis.
-aggressor <i>string</i>	Specifies the attackers which should be made quiet for given victim net(s). If no attacker is specified, all the aggressors of given victim(s) will be ignored. Note: If no victim is specified, the specified attackers are made quiet for all victim nets in the design.
-transition {rise fall}	Specifies the victim transition for which attackers will be assumed quiet. If no value is specified, attackers are skipped for both <code>rise</code> and <code>fall</code> transitions of the victim net.
-victim <i>string</i>	Specifies a list of victim nets for which attackers should be made quiet. Specific attackers can be skipped using the <code>-aggressor</code> option of this command. If the <code>-aggressor</code> option is not specified, all the attackers of the given nets are made silent and SI analysis will not be performed on these nets. Note: If this option is not specified, the attackers specified in the <code>-aggressor</code> option are made quiet for all the nets in the design.
-view <i>string</i>	Specifies the view for which attackers should be made quiet. If no view is specified, attackers are assumed quiet in all views

Examples

Consider a design having an attacker `agg` to victim nets `vic1` and `vic2`. The following command sets the attacker `agg` as quiet for both the victim nets `vic1` and `vic2`.

```
tempus > set_quiet_aggressor -aggressor {agg}
```

- The following command sets the attackers `A1` and `A2` as quiet when `V1` is rising during late analysis.

```
tempus > set_quiet_aggressor -victim V1 -aggressor A1 A2 -transition rise -analysis_type  
late
```

- The following command sets the attacker `A1` quiet for victim `V1` in the analysis view `VIEW1`. In this case, `A1` may be a valid attacker during SI analysis for victim `V1` in views other than `VIEW1`.

```
tempus > set_quiet_aggressor -victim V1 -aggressor A1 -view {VIEW1}
```

Consider a design having victim `vic` with attackers `agg1` and `agg2`:

- The following command sets both the attackers `agg1` and `agg2` as quiet for the victim net `vic`.

```
tempus > set_quiet_aggressor -victim {vic}
```

- The following command sets the attacker `agg1` as quiet for the given victim net `vic`

```
tempus > set_quiet_aggressor -aggressor {agg1} -victim {vic}
```

Related Commands

- [report_timing](#)

set_via_variation_mode

```
set_via_variation_mode  
[-help]  
[-reset]  
[-corner_sigma_multiplier <std::string>]  
[-correlation_type {corner}]  
[-reset {true | false}]  
[-separate_params_for_via {true | false}]
```

Allows you to scale via resistance from SPEF based on user-specified scaling factor.

This command allows you to specify per via sigma multiplier and handles the advanced via variation scaling.

Parameters

-help	Prints out the command usage
- corner_sigma_multiplier <std::string>	Provides the scaling multiplier for corner scaling. <i>Default:</i> " "
-correlation_type {corner}	Specifies inter-layer correlation values. <i>Default:</i> corner
-reset	Resets all or specified options to their default value.
-reset {true false}	Resets via variation modes to their default value. <i>Default:</i> false
- separate_params_for_via {true false}	Allows to create separate parameters for via variation. <i>Default:</i> false

Examples

- The following command uses correlation corner for scaling purpose:

```
set_via_variation_mode -view view1 -correlation_type corner -corner_sigma_multiplier  
{{{param_V1 -3} {param_V2 -3}..}}
```

where V1, V2 are via name and “-3” is used as scaling factor.

- The following command will scale the via resistance as shown below:

```
set_via_variation_mode -rc_variation false -corner_sigma_multiplier {{{param_V1 2}  
{param_V2 2}..}}
```

Via Calculation below:

```
Via1_Rnew = Via1_Rspef *(1 + 0.021 + 2*0.110)  
Via2_Rnew = Via2_Rspef *(1 + 0.010 + 2*0.120)
```

```
                Via1:  
table_meanshift: 0.021  
table_stdev :    0.110  
                Via2:  
table_meanshift: 0.010  
table_stdev :    0.120
```

To get the current value of any root attribute, use the `get_db` command:

- `get_db attribute_name`

To get the current value of all attributes in the `assign_pins` category, use the following command:

- `get_db -category si`

The SI attributes can be reported by using the following command:

- `get_db si_*`

si_accumulated_small_aggressor_factor

`si_accumulated_small_aggressor_factor double`

Default: 1.0

Data_type: Double

Specifies the multiplication factor that controls the effect of the cap mode accumulated small attacker. An accumulated small attacker is an imaginary attacker that represents the sum of all the weak attackers on a specified net. To reduce the pessimism of using the accumulated small attacker, adjust this value to anything between 0 and 1. A value of 0 means that the cap mode accumulated small attacker will not be used.

Note: This option does not work with the current mode accumulated small attacker, which is default for process sizes 45nm and below.

si_accumulated_small_aggressor_mode

`si_accumulated_small_aggressor_mode {cap | current | zero_mean | numerical}`

Default: {}

Data_type: Enum

Specifies whether to use the current matching based method for accumulated small attackers. You can specify the following options:

- `cap`: Uses the accumulated small attacker method, which matches the total coupling capacitance of an attacker with the small attackers that are being virtualized. This is the default mode for all process nodes above 45nm.
- `current`: Uses the current matching based method for accumulated small attackers. With this method, the transitions on virtual attackers are modeled using Piece Wise Linear (PWL) waveforms. The PWL waveforms are generated in a way that the current induced by the transition matches the total current induced by all accumulated small attacker components.

- `zero_mean`: Uses the accumulation method where series of small attackers (that is, attackers with less than the individual attacker threshold value), are assumed to transition in opposing directions and cancel one another in aggregate.

Note: For 45nm and below process nodes, the default value is `current`.

si_accumulated_small_aggressor_threshold

`si_accumulated_small_aggressor_threshold` *double*

Default: 10.01

Data_type: Double

Sets the accumulated small attacker glitch threshold. If the virtual attacker produces a glitch whose peak is below this threshold, the component coupling capacitors of the accumulated small attacker are split into two ground capacitors and there is no accumulated small attacker for the victim. The value is specified as a ratio of VDD. To disable the accumulated small attacker, you must set a value greater than 1.

si_aggressor_alignment

`si_aggressor_alignment` {`path` | `path_overlap` | `timing_aware_edge` | `input_arrival`}

Default: `input_arrival`

Data_type: Enum

Specifies the attacker alignment. You can specify the following options:

- `path`: The victim worst arrival edge is used while determining the attackers. Crosstalk impact is computed according to the latest/earliest arrival edge of victim for max/min analysis.
- `path_overlap`: The full timing window of victim is considered while determining the attackers. Crosstalk impact is calculated according the victim edge, lying anywhere in timing window, which may experience maximum impact.
- `timing_aware_edge`: Realistic analysis similar to path-based analysis is performed. Each attacker's impact is annotated on victim transition where attacker timing window edge aligns with the victim. However, to ensure GBA bounds PBA analysis, the timing-aware edge mode handles some nets based on their timing properties in GBA analysis.
- `input_arrival`: The attackers use timing windows formed by 2-sigma arrivals regardless of the analysis sigma multiplier. The victim driver input arrivals will be used for SI computation. Also, the mean victim timing window and edge will be used for SI computation in GBA and PBA modes, respectively. This behavior allows pessimism reduction in GBA SI analysis with narrower timing windows. And provides a more accurate PBA SI analysis, with no dependency of driver cell GBA

delays.

For more information, refer to the [Attacker Selection Based on Alignment](#) section in the *Tempus Stylus User Guide*.

si_clock_synchronicity

```
si_clock_synchronicity {asynchronous | synchronous}
```

Default: synchronous

Data_type: Enum

Treats the clocks either synchronous or asynchronous to each other.

si_delay_clock_delta_threshold

```
si_delay_clock_delta_threshold double
```

Default: -1.0

Data_type: Double

Specifies the clock delta delay analysis threshold value.

si_delay_delta_threshold

```
si_delay_delta_threshold double
```

Default: -1.0

Data_type: Double

Specifies the delta delay analysis threshold value.

si_delay_delta_annotation_mode

```
si_delay_delta_annotation_mode {lumpedOnNet | arc}
```

Default: arc

Data_type: Enum

Calculates the delay for each arc (cell arc and net arc) in a path. By default, AAE calculates the delay, including SI for each arc and if the user chooses to view the SI delay separately, it would show annotated to each arc.

Alternatively, you can choose to annotate the SI delay solely to the net. In this case, the worst-case arc is used to calculate the SI delay and it is annotated solely to the net.

- `lumpedOnNet`: Lumps the delta delay on a the net, if it is broken out.
- `arc`: Separates the delta delay on each cell arc and net arc, as calculated.

si_delay_enable_double_clocking_check

```
si_delay_enable_double_clocking_check {true | false}
```

Default: false

Data_type: Boolean

Enables double clocking check in AAE.

This option enables double clocking analysis and `report_double_clocking` command can be run to print a report.

si_delay_enable_logical_correlation

```
si_delay_enable_logical_correlation {true | false}
```

Default: false

Data_type: Boolean

Enables the AAE-SI logical correlation. Logical correlation refers to correlation of logic between (aggressor) nets which are connected to each other. A simple case would be input and output nets of an inverter never switch in the same direction, so cannot be attackers to the same net simultaneously.

si_delay_enable_report

```
si_delay_enable_report {true | false}
```

Default: false

Data_type: Boolean

Enables SI delay reports.

si_delay_only

```
si_delay_only {true | false}
```

Default: false

Data_type: Boolean

Performs noise-on-delay analysis exclusively. This means that when you use this parameter, the software does not perform glitch analysis and only performs noise-on-delay analysis. In addition, this

parameter performs SI analysis.

si_delay_separate_on_data

```
si_delay_separate_on_data {true | false}
```

Default: false

Data_type: Boolean

Separates incremental delays on signal nets.

si_delay_double_switching

```
si_delay_double_switching {none | clock | data_sequential | all}
```

Default: none

Data_type: Enum

Specifies the type of data (clock, data sequential, or all) for which double switching analysis will be performed.

si_enable_advanced_flow

```
si_enable_advanced_flow {true | false}
```

Default: false

Data_type: Boolean

Enables advanced SI analysis.

When set to `true`, the advanced SI analysis flow is enabled, in which attacker slews are computed by establishing a signoff-accurate base delay calculation before SI analysis begins. Apart from accuracy benefits, it also provides runtime benefits through enhanced reuse from signoff-accurate base iteration.

When set to `false`, a fast pre-SI analysis is performed for attacker slew computation.

si_enable_bus_attacker_correlation

```
si_enable_bus_attacker_correlation {true | false}
```

Default: false

Data_type: Boolean

Enables the software to treat bits of bus as correlated attackers.

When set to `true`, the bits of bus type nets are grouped together based on their cumulative weight.

The bus bits that act as attackers to a specific victim are treated as a group. All the attackers are grouped into different bundles where normal (non-bus) attackers form one group and bits of the same bus form multiple other groups. In case of a victim that has a number of small couplings to bits of a bus, the combined effect of a full bus can be used to decide whether an attacker is significant.

si_enable_drv_with_delta_slew

```
si_enable_drv_with_delta_slew {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, the `max_transition` violations are reported based on the SI slews. Also, this allows SI slew reporting/fixing by the `opt_signoff` command and is applied prior running the `write_eco_opt_db` command.

si_enable_glitch_overshoot_undershoot

```
si_enable_glitch_overshoot_undershoot {true | false}
```

Default: `false`

Data_type: Boolean

Enables glitch overshoot/undershoot.

si_enable_glitch_propagation

```
si_enable_glitch_propagation {true | false}
```

Default: `false`

Data_type: Boolean

Enables glitch propagation through single stage cells and driver weakening through single stage and dual stage cells. When this attribute is set to `true`, the software does not delete the glitch waveform saved on instance input pins. The waveform is later used by spice deck to propagate glitch at the next stage receiver pin.

si_enable_glitch_propagation_spice_deck

```
si_enable_glitch_propagation_spice_deck {true | false}
```

Default: `false`

Data_type: Boolean

Enables the driver input glitch waveform to be printed in the SPICE deck such that SPICE can also perform single stage glitch propagation. When this option is set to `true`, the software does not delete the glitch waveform saved on instance input pins. The waveform is later used by spice deck to propagate glitch at the next stage receiver pin.

si_enable_lle_glitch

```
si_enable_lle_glitch {true | false}
```

Default: `false`

Data_type: Boolean

Enables SI glitch analysis for LLE.

si_enable_two_stage_driver_weakening

```
si_enable_two_stage_driver_weakening {true | false}
```

Default: `true`

Data_type: Boolean

Enables the two-stage driver weakening mode.

A non-failing significant glitch at the input of a two-stage driver can propagate through the first stage and weaken the second stage. This might cause the crosstalk-induced glitch to amplify at the next stage receiver (though it may not be significant enough to propagate). When two-stage driver weakening is enabled, the software considers weakened holding resistance for the two-stage driver for glitch analysis.

The dual stage driver weakening honors the glitch propagation threshold criteria.

Note: This feature is supported with CCS-N models only.

si_max_virtual_attacker_constituents

```
si_max_virtual_attacker_constituents integer
```

Default: `5`

Data_type: Integer

Specifies the maximum number of virtual attacker constituents to report.

si_enable_user_defined_bus_merging

`si_enable_user_defined_bus_merging {true | false}`

Default: false

Data_type: Boolean

Enables the bus merging feature. If a net is in two groups, then the groups will be merged.

si_enable_virtual_attacker_constituent_report

`si_enable_virtual_attacker_constituent_report {true | false}`

Default: false

Data_type: Boolean

Enables virtual attacker constituent reporting.

The software provides support for virtual attacker constituent reporting (when the bus attacker correlation feature is enabled using the `si_enable_bus_attacker_correlation` attribute).

The virtual attacker constituent reporting feature is useful for identifying significant buses and their bits - this information can be used for glitch fixing.

si_glitch_accuracy_level

`si_glitch_accuracy_level int`

Default: 0

Data_type: Integer

Specifies the accuracy levels for glitch analysis.

si_glitch_analysis_type

`si_glitch_analysis_type {source | full_propagation}`

Default: source

Data_type: Enum

Specifies the glitch analysis type - `source` or `full_propagation`.

- `full_propagation`: Propagates glitch noise through single and 2-stage cells with CCSN (for example, `inv` or `buf`), and stops glitch propagation at any sequential cell, or 3 or more stage cell input.

- **source:** Propagates glitch through 1-stage cells only, and performs driver weakening through 2-stage cells with CCSN.

si_glitch_constrained_input_threshold_failure_point

si_glitch_constrained_input_threshold_failure_point {input | both}

Default: input

Data_type: Enum

Allows you to control the glitch failure criteria when a user specifies an object-specific RIP threshold.

When set to `input`, the software skips ROP analysis and performs RIP-based failure check on the receiver pins for cases where object-specific RIP threshold is set using the `set_glitch_threshold - failure_point input -net` (or `-pin`) command.

When set to `both`, the software performs both RIP and ROP failure checks, wherever possible. If user-specified RIP failure criteria is violated, then it will be flagged as a RIP violation. If RIP criteria passes and receiver noise models exist, then the ROP is computed and checked against the ROP failure threshold for failure determination.

For the following cases where the object-specific RIP thresholds are not specified, the attribute behavior remains unchanged:

- For receiver pins with noise models present, ROP-based failure check is performed. The RIP-based failure criteria is not checked at all.
- For receiver pins with noise models missing, the RIP-based failure criteria is checked for violations.

si_glitch_enable_dynamic_receiver_peak_limits

si_glitch_enable_dynamic_receiver_peak_limits {true | false}

Default: false

Data_type: Boolean

Enables automatic computation of ROP threshold value of two-stage cells, using the CCS-noise data on timing arcs.

When set to `true`, the software computes the noise threshold of the last stage from the table of DC currents.

si_glitch_enable_report

si_glitch_enable_report {true | false}

Default: false

Data_type: Boolean

Enables the storage of glitch information for further debug using the `report_noise` command.

When set to `false`, the `time_design` command will still report glitches in the `timingReports/*.SI_Glitches.rpt` file but the `report_noise` command will not be available for use.

When set to `true`, the `report_noise` command may be used and glitch information will be more aligned to Tempus signoff values.

si_glitch_input_full_propagation_threshold

`si_glitch_input_full_propagation_threshold double`

Default: 0.75

Data_type: Double

Specifies the receiver input glitch threshold beyond which Tempus will not propagate the glitch in full-propagation mode, and an RIP violation will be flagged.

si_glitch_input_full_propagation_voltage_high_threshold

`si_glitch_input_full_propagation_voltage_high_threshold double`

Default: 0.75

Data_type: Double

Specifies the receiver VH input glitch threshold beyond which Tempus will not propagate the glitch in full-propagation mode, and an RIP violation will be flagged.

This attribute takes precedence over `si_glitch_input_full_propagation_threshold`.

si_glitch_input_full_propagation_voltage_low_threshold

`si_glitch_input_full_propagation_voltage_low_threshold double`

Default: 0.75

Data_type: Double

Specifies the receiver VL input glitch threshold beyond which Tempus will not propagate the glitch in full-propagation mode, and an RIP violation will be flagged.

This option takes precedence over `si_glitch_input_full_propagation_threshold`.

These attributes are applicable only when the full propagation mode is enabled (using the `si_glitch_analysis_type full_propagation` attribute).

si_glitch_input_threshold

`si_glitch_input_threshold double`

Default: 0.4

Data_type: Double

Specifies the input glitch failure threshold value during AAE analysis.

si_glitch_input_voltage_high_threshold

`si_glitch_input_voltage_high_threshold double`

Default: 0.4

Data_type: Double

Specifies the input glitch vh failure threshold value during AAE analysis. The value is the fraction of local VDD – if VDD is 0.9V and the threshold is 0.4, then the criteria for failure is $0.4 * 0.9 = 0.36V$.

During timing window re-convergence, only certain nets are reselected for glitch analysis in each iteration (if any of the above input glitch threshold parameters is specified). The criteria for glitch reselection is based on the specified input glitch threshold value, if this value is smaller than 30% of VDD. If not, then all the glitches larger than 30% of VDD are selected for re-computation in each iteration.

si_glitch_input_voltage_low_threshold

`si_glitch_input_voltage_low_threshold double`

Default: 0.4

Data_type: Double

Specifies the input glitch vl lower threshold value during AAE analysis. The value is a fraction of the local VDD - if VDD is 0.9V and the threshold value is 0.4, then the criteria for failure is $0.4 * 0.9 = 0.36V$.

During timing window re-convergence, only certain nets are re-selected for glitch analysis in each iteration (if any of the above input glitch threshold parameters is specified). The criteria for glitch reselection is based on the specified input glitch threshold value, if this value is smaller than 30% of VDD. If not, then all the glitches larger than 30% of VDD are selected for re-computation in each iteration.

si_glitch_receiver_clock_peak_limit

`si_glitch_receiver_clock_peak_limit double`

Default: 0.05

Data_type: Double

Defines the glitch check limit for latch inputs in receiver peak mode. This parameter is specified as a ratio of VDD.

si_glitch_receiver_latch_peak_limit

`si_glitch_receiver_latch_peak_limit double`

Default: 0.1

Data_type: Double

Defines the receiver peak/glitch peak limit at all nodes. The value specified for this parameter is a ratio of VDD.

si_glitch_receiver_peak_limit

`si_glitch_receiver_peak_limit double`

Default: 0.15

Data_type: Double

Defines the receiver peak/glitch peak limit.

si_individual_aggressor_simulation_filter

`si_individual_aggressor_simulation_filter {true | false}`

Default: true

Data_type: Boolean

Uses electrical filtering to reduce pessimism due to small attackers being preserved when their simulated value is under the individual attacker threshold value.

Note: This option can only be used when the accumulated small attacker is turned off (`accumulated_small_attacker_threshold` is 1.00 or larger).

si_individual_aggressor_threshold

`si_individual_aggressor_threshold double`

Default: 1.5% or 0.015

Data_type: Double

Sets the glitch tolerance for individual attacker nets on the victim net. Tempus estimates the noise

contributed by an individual attacker on the victim. If the peak of this noise exceeds the value of `individual_attacker_threshold`, the attacker is significant and is individually reported in the constituents section of the report. Otherwise, this aggressor becomes eligible for the virtual attacker. If the virtual attacker peak does not exceed the value of `accumulated_small_attacker_threshold`, the aggressor nets in the virtual attacker are grounded and there is no virtual attacker.

Note: Minimum allowed individual attacker to be kept is 0.1% of VDD, which is equivalent to an `individual_attacker_threshold` of 0.001.

si_individual_aggressor_clock_threshold

`si_individual_aggressor_clock_threshold double`

Default: 0.015

Data_type: Double

Defines the AAE virtual attacker clock threshold.

si_nonlinear_aggressor_slew

`si_nonlinear_aggressor_slew {true | false}`

Default: true

Data_type: Boolean

Uses a non-linear attacker. If set to false, the software uses a linear attacker.

si_num_iteration

`si_num_iteration int`

Default: 2

Data_type: Integer

Specifies the maximum number of timing window iterations that should be performed during SI delay analysis. Performing delay analysis results in changes to the timing windows, which can potentially change the victim/attacker net combinations. Timing window iterations enable the software to reach to a point where the delay changes are negligible.

Note: The minimum allowed timing window iterations is 2 for performing SI analysis.

si_reselection

`si_reselection {delta_delay | slack | xcap_ratio}`

Default: slack

Data_type: Enum

Specifies the SI reselection criteria during timing window iterations.

- **delta_delay:** Reselects a net for calculation if the delta delay on the net is greater than the delay value.
- **slack:** Reselects nets that have failing slacks during timing window iterations.
- **xcap_ratio:** Specifies the xcap ratio.

si_reselection_delay_threshold

`si_reselection_delay_threshold double`

Default: 1e-11 (seconds)

Data_type: Double

Allows you to change the delay reselection criteria.

si_reselection_hold_slack

`si_reselection_hold_slack double`

Default: -1e-12 (seconds)

Data_type: Double

Specifies the slack reselection threshold for hold.

si_reselection_setup_slack

`si_reselection_setup_slack double`

Default: -1e-12 (seconds)

Data_type: Double

Specifies the slack reselection threshold for setup.

si_secondary_attacker_decoupling_factor

`si_secondary_attacker_decoupling_factor double`

Default: 1.0

Data_type: Double

Specifies decoupling factor for secondary aggressors.

si_skip_noise_model_check

si_skip_noise_model_check string

Default: " "

Data_type: String

Specifies the list of pins for which noise model check will not take place.

si_skip_timing_window

si_skip_timing_window string

Default: " "

Data_type: String

Specifies the list of nets for which timing window is to be skipped. The timing window becomes infinite for the net when it is both a victim and aggressor.

When specified, only the last setting is retained.

si_switch_probability

si_switch_probability double

Default: 0.3

Data_type: Double

Sets the attacker switching probability. If you specify a value less than 0.0 or more than 1.0 , the switching probability is automatically set to the default value of 0.3.

si_unconstrained_net_use_infinite_timing_window

si_unconstrained_net_use_infinite_timing_window {true | false}

Default: true

Data_type: Boolean

Specifies that unconstrained nets will have an infinite timing window. To turn this off and use a constrained timing window, set this to *false*.

si_use_infinite_timing_window

```
si_use_infinite_timing_window {true | false}
```

Default: false

Data_type: Boolean

Uses infinite timing windows in a single SI run.

si_virtual_inter_die_attacker_slew

```
si_virtual_inter_die_attacker_slew value
```

Default: 2.5e-11

Data_type: Float

Specifies the virtual inter-die attacker slew value.

update_glitch

```
update_glitch  
[-help]  
[-effort {medium | high}]
```

Allows you to run glitch analysis without running SI delay analysis. This command provides the ability to run glitch analysis on all the nets in a design or on a subset of nets.

Using the `update_glitch` command without `report_timing` or `update_timing` will only run glitch analysis.

Note: It is not recommended to run the `update_glitch` command after the `report_timing` or `update_timing` command.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>update_glitch</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man update_glitch</code> .
<code>-effort</code> <code>{medium</code> <code> high}</code>	Specifies the effort level for update glitch. When set to <code>high</code>, glitch analysis uses more accurate modeling of glitch for small attackers, thereby reducing pessimism. Note: The run time in <code>high</code> mode may be slightly higher, and is largely dependent on the distribution of coupling. <i>Default:</i> <code>medium</code>

Examples

- The following command will run glitch analysis without SI delay:
`> update_glitch`

Related Commands

- `report_noise`
- `report_timing`
- `update_timing`

write_noise_eco_nets

```
write_noise_eco_nets  
[-help]  
out_file  
[-problem_nets <string>]
```

Tempus performs ECO analysis for noise failures. The default ECO file is named `glitch`.

Note: The `write_noise_eco_nets` command should always be called after glitch analysis has been performed.

Parameter

<code>-help</code>	Prints out the command usage.
<code>out_file</code>	Specifies the name for the ECO file. By default, the file name is <code>glitch</code> .
<code>-problem_nets <string></code>	Reports on the specified list of net names.

Examples

The following command generates an ECO file for all the glitch failures.

```
tempus> write_noise_eco_nets glitch_eco.txt
```

```

Generates the SPICE trace for a path.

While generating a Spice Deck, the `write_spice_deck` command looks for library cells required to run Spice and adds all cells as ".include" in the generated Spice netlist.

The output SPICE deck includes:

- Active and passive devices such as field-effect transistors (FETs), capacitors, and resistors.
- Initial conditions and voltage sources
- Actual names of the gates, nets, and cell instances, which helps the simulator interpret this information effectively. For example, consider the following excerpt, which shows an entry for a gate named `U0` in the SPICE deck:

```
*Gate U0
```

```
*-----
*Cell ports in order : x a VSS VDD
*-----
XU0 U0/x U0/a 0 U0/VDD inv_ahvt_64
*-----
```

Note: By default, the software uses the default list of power node names (VDD and VCC) and ground node names (GND and VSS).

Note: In order to output a Spice deck that generates the same report output as the `report_timing` command, you must run the `write_spice_deck` command with the `-report_timing`, `-segment_start`, and `-segment_end` parameters.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-add_driver_for_constraint_check {true false}</code>	Enables constraint check deck generation with pre-dr
<code>-add_side_load_measurement {true false}</code>	Adds the side load measurement in clock mesh Spice deck. By default, Tempus only measures the latencies, delays and slews of arcs that are part of clock mesh specified using the <code>-from</code> parameter. When set to true, the software additionally measures latencies and slews of the side receivers at each stage. <i>Default:</i> false
<code>-add_voltage_for_missing_sensitization</code>	Adds the voltage for missing sensitization.
<code>-aging_correlation_type {full timingonly}</code>	Creates the aging-aware Spice deck. <code>timingonly</code>: Writes out the Spice deck for timing-only correlation mode. The Spice deck contains device degradation parameters computed by Tempus. <code>full</code>: Writes out the Spice decks for full correlation. This involves two Spice simulations. The first Spice simulation computes device degradation using static simulation. The second Spice simulation uses this data for transient simulation, where delays and slews are measured for timing correlation.

<code>-aging_stress_num_cycles <integer greater than 0></code>	Specifies the number of cycles in stress simulation in Spice correlation mode. When this parameter specified, the periodic stress waveform propagates through the entire path on which correlation is required. It is recommended to use the value 6, which is based on the path depth.
<code>-aging_stress_use_timing_slew {false true}</code>	Uses the slew from STA in stress Spice deck for full S correlation, instead of using the default slew of 1ps.
<code>-aging_level_only <string></code>	Indicates the type of aging, such as BTI, HCI, or both. parameter is required for URI models only. Note: The exact value of aging level is foundry specific.
<code>-bbox_cells <i>string</i></code>	Specifies a list of cells to be considered as black boxes.
<code>-clock_mesh_depth <i>integer</i></code>	Creates clock mesh spice deck of depth.
<code>-clock_mesh_from_fall_pin <i>string</i></code>	Creates the spice deck with mesh net starting from fall transition of specified from pin.
<code>-clock_mesh_from_pin <i>string</i></code>	Creates the spice deck with mesh net starting from pin.
<code>-clock_mesh_from_rise_pin <i>string</i></code>	Creates the spice deck with mesh net starting from rise transition of specified from pin.
<code>-clock_mesh_no_hard_stop_at_to_pins {true false}</code>	When it is <code>true</code>, it will traverse down all the way till it hits the clock pin of a flip-flop or or if it passes the depth specified with the <code>-depth</code> parameter.
<code>-clock_mesh_to_pin <i>string</i></code>	Creates the spice deck with mesh net ending at to pin.
<code>-constraint_check {true false}</code>	Enables constraint check deck generation.

<pre>-enable_fast_simulation {true false}</pre>	When set to <code>true</code>, the software enables the fast simulation mode. In this mode, additional clock cycles are not required to initialize sequential cells in the Spice deck; this speeds up Spice simulations. All the sequential cells are initialized using the initial conditions and only a single clock edge is applied as input. By default, this parameter is set to <code>false</code>. In this mode two clock cycles are applied as input to the clock network where the first triggering edge is used for initialization of sequential cells, and the second edge is used for delay measurement. Note: For better performance with sequential cell simulations, you can set the <code>-enable_fast_simulation</code> parameter to <code>true</code> during constraint check generation.
<pre>-enable_spectre_x {true false}</pre>	Enables the spectreX license checkout when launching Spectre.
<pre>-enable_mis {tied_input independent_input none}</pre>	Enables advanced multi-input switching (AMIS) during Spice deck creation. You can specify one of the following options: • <code>tied_input</code>: Multiple inputs of an instance will be tied together in a netlist. You can set the <code>timing_analysis_multi_input_switching_mode</code> attribute to 1 to enable this behavior. • <code>independent_input</code>: Allows the Spice deck to write input stimulus for side inputs for multi-input gates. switching times of each input depends on the timing windows. This option can be used when the <code>timing_analysis_multi_input_switching_mode</code> attribute is set to 2. • <code>none</code>: Disables AMIS during the Spice deck creation. <i>Default:</i> none
<pre>-exclude_side_load_cells string</pre>	Specifies a list of cells for which the pin capacitance values be used for side loads instead of instantiating them.
<pre>-exclude_side_load_cells_for_missing_subckt {true false}</pre>	When set to <code>true</code>, the software will add side load pin capacitance for missing Spice subckt cell instead of instantiating it.

<code>-force_delete_output_dir</code>	Completely removes the directory specified by the user using the <code>-out_dir</code> parameter.
<code>-generate_output_only {true false}</code>	Generates the report output only, without triggering any simulations. <i>Default:</i> false
<code>-glitch_simulation_mode {input_output output}</code>	Specifies the glitch simulation mode. When set to <code>input_output</code> , the software uses both the <code>input</code> and <code>ROP</code> for Spice calculations. When <code>output</code> is specified, the Spice <code>ROP</code> will be computed using the <code>RIP</code> .
<code>-glitch_receiver_pin string</code>	Specifies receiver pin for glitch spice deck.
<code>-ground_nets string</code>	Specifies a list of ground nodes.
<code>-include_cell_variation {true false}</code>	Writes out the Spice deck required to run simulations. When set to <code>true</code> , the software runs Monte-Carlo simulations from within the Tempus software. <i>Default:</i> false
<code>-lsf_job_string string</code>	Specifies a handle to the farm job for launching the simulation.
<code>-monte_carlo_sim_init_args string</code>	Passes necessary Monte Carlo parameters that are required to run MC simulations. The Monte Carlo analysis refers to “statistics blocks”, where statistical distributions and correlations of netlist parameters are specified. This parameter initializes these parameters under the statistics block. Note: This parameter can be used when <code>-include_cell_variation</code> is set to <code>true</code> .
<code>-monte_carlo_sim_transient_args string</code>	Initializes full transient time of simulation and transient time step.
<code>-measure_point {all path stage}</code>	Specifies whether to add all, path, or stage measurements. <i>Default:</i> all
<code>-merge_spice_deck {true false}</code>	Allows you to enable merged Spice deck.

<code>-omipath <string></code>	Specifies the OMI (Open Model Interface) directory - required only for OMI.
<code>-out_dir <i>string</i></code>	Specifies the name of the output directory that will contain the generated delay and/or glitch spice decks. If simulation is also performed using the <code>-run_simulation</code> parameter, the Spice simulations output will also be saved in this directory. <i>Default:</i> <code>tempus_pathsim</code>
<code>-out_file_prefix <i>string</i></code>	Adds the specified prefix to the generated Spice deck files. If this parameter is not used, one of the following default names of the generated Spice decks will be used: • <code>path_<index>_setup.sp</code>: for setup paths • <code>path_<index>_hold.sp</code>: for hold paths • <code>path_<index>_vl_glitch.sp</code>: for VL glitch • <code>path_<index>_vh_glitch.sp</code>: for VH glitch The <code><index></code> in the above file names is controlled based on the number of decks that are generated using the <code>write_spice_deck</code> command. A user-specified string (specified using this parameter) used as a prefix to the above mentioned file names.
<code>-power_nets <i>string</i></code>	Specifies list of power nodes.

<code>-reliability_commands</code> <i>string</i>	Allows you to specify the analysis type. Spice deck creation while using OMI models requires to provide the following strings using the <code>-reliability_commands</code> parameter, to direct the Spice simulator for the appropriate analysis. The following three Spice parameters need to be defined as per the required analysis type: <table><tr><th>Analysis</th><th>bti_on</th><th>hci_on</th><th></th></tr><tr><td>btirec</td><td></td><td></td><td></td></tr><tr><td>BTI-Only</td><td>1</td><td>0</td><td>(</td></tr><tr><td>BTI-Only with Recovery</td><td>1</td><td>0</td><td></td></tr><tr><td>HCI-Only</td><td>0</td><td>1</td><td>(</td></tr><tr><td>BTI+HCI without Recovery</td><td>1</td><td>1</td><td></td></tr><tr><td>BTI+HCI with Recovery</td><td>1</td><td>1</td><td></td></tr></table> A few examples are given below: BTI-only without recovery: <pre>-reliability_commands ".param hci_on=0 bti_on=1 she_on=0 btirec_on=0"</pre> HCI-only: <pre>-reliability_commands ".param hci_on=1 bti_on=0 she_on=0 btirec_on=0"</pre> BTI+HCI without recovery: <pre>-reliability_commands ".param hci_on=1 bti_on=1 she_on=0 btirec_on=0"</pre> BTI-only with recovery: <pre>-reliability_commands ".param hci_on=0 bti_on=1 she_on=0 btirec_on=1"</pre> BTI+HCI with recovery: <pre>-reliability_commands ".param hci_on=1 bti_on=1 she_on=0 btirec_on=1"</pre> Note: HCI support for OMI is not available.	Analysis	bti_on	hci_on		btirec				BTI-Only	1	0	(	BTI-Only with Recovery	1	0		HCI-Only	0	1	(	BTI+HCI without Recovery	1	1		BTI+HCI with Recovery	1	1	
Analysis	bti_on	hci_on																											
btirec																													
BTI-Only	1	0	(																										
BTI-Only with Recovery	1	0																											
HCI-Only	0	1	(																										
BTI+HCI without Recovery	1	1																											
BTI+HCI with Recovery	1	1																											
<code>-reliability_model_type</code> {URI OMI TMI}	Specifies the aging-aware deck type - URI, OMI, or TM																												

<code>-report_fields <i>string</i></code>	Changes run path simulation internal reporting format. The format columns should be compatible with those of the <code>report_timing_format</code> attribute. These settings will be used for the subsequent <code>write_spice_deck</code> command statement.
<code>-report_noise_cmd <i>string</i></code>	Specifies the <code>report_noise</code> command parameters as a list of arguments within brackets. When specified, the Spice deck will be generated for the receiver pins that are reported by the <code>report_noise</code> command for the specified options. When specified with the <code>-run_simulation</code> parameter, software writes out a comparison report comparing various glitch parameters between Tempus and Spice, such as, RIP, input glitch area, and ROP (only if ROP node name is available in the noise models).
<code>-report_timing_cmd <i>string</i></code>	Specifies arguments to <code>report_timing</code> command.
<code>-run_simulation</code>	Enables path simulation in addition to generating Spice Deck.
<code>-scale_mode <i>string</i></code>	Allows you to specify the UMC_URI scale mode option. <i>Default: effective</i>

<pre>-segment {data_path launch_path launch_clock_path capture_path all}</pre>	Creates the Spice deck of a segment out of the path s deck. The following command/global variable settings have following impact on the <code>-segment</code> parameter options: • <code>-path_type full_clock</code> is defined under the <code>write_spice_deck-report_timing</code> parameter, then the segment default value is <code>launch_path</code>. • <code>-path_type full_clock</code> is not specified, then default value is <code>data_path</code>. • <code>timing_disable_retime_clock_path_slew_propaga</code> attribute is set to <code>false</code>, the default value is <code>launch_path</code> (irrespective of <code>-path_type</code> settings). • <code>timing_disable_retime_clock_path_slew_propaga</code> attribute is set to <code>true</code> (default), then <code>launch_clock_path</code> and <code>capture_path</code> options are supported only when the <code>-path_type full_clock</code> option of the <code>write_spice_deck -report_timing</code> parameter is used.
<pre>-segment_end string</pre>	Specifies the name of the segment end term.
<pre>-segment_start string</pre>	Specifies the name of the segment start term.
<pre>-si_sweep_range float</pre>	Range to sweep the victim.
<pre>-si_sweep_steps integer</pre>	Number of steps by which the victim is swept.
<pre>-si_sweep_victim {true false}</pre>	Enables victim sweep.
<pre>-side_path_levels integer</pre>	Specifies side path level.
<pre>-spectre_analysis_options <string></pre>	Adds Spectre analysis options to the run. When specified the software provides instructions to Spectre, e.g., run session with extra accuracy.
<pre>-spectre_cmd_options string</pre>	Specifies command line options for Spectre.
<pre>-spectre_exe_path string</pre>	Specifies location of Spectre path.
<pre>-spice_include_file string</pre>	Specifies the string to be included in the generated spice deck.

<code>-spice_model_files <i>string</i></code>	Specifies the name of the model files to be included in the generated spice.
<code>-spice_stimuli_file <i>string</i></code>	Allows you to specify the file path containing stimuli to be used for the specified library cells. The cells' sensitization coming from the user-specified stimuli file takes precedence over Tempus inferred sensitization. Syntax for delay Spice decks is given below: <code>lib_cell <i>string</i> <from from_rise from_fall> <i>string</i> <to to_rise to_fall> <i>string</i> input_vector <i>string</i> num_clk_pulse <i>integer</i></code> Syntax for glitch Spice decks is given below: <code>lib_cell <i>string</i> glitch_type <VL VH> output_pin <i>string</i> input_vector <i>string</i> num_clk_pulse <i>integer</i></code> For victim driver sensitization <code>lib_cell <i>cell_name</i> glitch_type <VL VH> input_pin <i>string</i> input_vector <i>string</i> num_clk_pulse <i>integer</i></code> For victim receiver sensitization The <code>num_clock_pulse <i>integer</i></code> holds significance in case of sequential arcs, and specifies where to align the data pin transition with respect to the clock transition. For example, a value of '1' (default setting) specifies that the data pin transition needs to be aligned before the clock transition where delay measurement is intended. This value can be used in case of regular flip-flops. The value '2' specifies that data pin transition needs to be aligned with respect to the second-last triggering clock edge. This value can be used for cascaded 2-bit flip-flops. Additionally for sequential arcs, the first pin in the user-specified input vector needs to be the data pin, the signal of which will be latched in the sequential cell. Here are some examples of stimuli file: The following example shows the stimuli file containing sensitization for CP(rise)->Q(fall) and CP(rise)->Q(rise) timing arcs of library cell FF1: <pre>lib_cell FF1 from_rise CP to_fall Q input_vector !D&CDN&!SE&!SI num_clk_pulse 2 lib_cell FF1 from_rise CP to_rise Q input_vector D&CDN&!SE&!SI num_clk_pulse 2</pre>

	The following example shows the stimuli file containing sensitization for the victim driver cell AC for both VL and VH glitches: <pre>lib_cell AOI glitch_type VL output_pin Z input_vector !A&!B&!C lib_cell AOI glitch_type VH output_pin Z input_vector A&!B&C</pre>
<code>-spice_subckt_files <i>string</i></code>	Specifies the subckt file, to be included in generated spice.
<code>-supply_voltage_file <i>string</i></code>	Specifies the file containing user-specified power/gro voltages to be used for SPICE simulations. By default design operating voltages will be used. The format of the supply voltage file is as follows: <pre>GLOBAL POWER #Specifies the global supply for all pow pins</pre> <pre>GLOBAL GROUND #Specifies the global supply for all gro pins</pre> <pre>GLOBAL #Specifies the voltage to be used for given pg for all instances</pre> <pre>POWER #Specifies the VDD to be used for specified I/O PWLs</pre> <pre>GROUND #Specifies the VSS to be used for specified I/C port PWLs</pre> <pre>POWER / #Specifies the VDD used for specified instanceAC/AEURAtms signal pin PWL or sensitizatic</pre> <pre>GROUND / #Specifies the VSS used for specified instanceAC/AEURAtms signal pin PWL or sensitizatic</pre> <pre>/ #Specifies the voltage used for specified instanceAC/AEURAtms pg pin</pre>
<code>-supply_voltage_file_stress <file></code>	Specifies an optional extra file containing the stress voltages for supply or ground pins that are in cell sub-circuit definition.
<code>-through <i>string</i></code>	Creates the Spice deck with mesh net going by – through points.

<code>-temperature float</code>	Specifies a user-defined temperature to be used in SPICE simulations. <i>Unit:</i> Celsius
<code>-uri_lib_file string</code>	Specifies the URI model file (required only for URI). <i>Default:</i> none
<code>-uri_mode string</code>	Specifies the URI appendage option. <i>Default:</i> appendage
<code>-use_control_param {true false}</code>	Allows you to control the power/ground voltage levels the created Spice deck through user-specified parameters. When set to <code>true</code>, an additional file with the same name as the deck, and extension <code>.control</code> is created that contains the parameterized design voltage levels of the PG pins of all the cells instantiated in the deck. You can modify the <code>*.control</code> file as per the requirement without modifying the original deck.
<code>-use_distributed_load_for_side_receivers {true false}</code>	Allows you to control whether to use the receiver output load as distributed or lumped load. <i>Default:</i> false
<code>-user_defined_measure_statements {append overwrite}</code>	Specifies whether to overwrite the default measurement statements in the Spice deck by user-defined measurements specified using the <code>-user_defined_measure_statements_file</code> parameter, or append it with default measure statements. <i>Default:</i> append

<code>-user_defined_measure_statements_file string</code>	Allows you to add the delay/slew measurement statements for any given segment of the path for which Spice deck is generated. The format of the file is given below: <MEASURE_TAG_NAME TRIGGER_PIN_NAME TARGET_PIN_NAME Multiple such lines with unique tags can be specified the file. The measure statement is written in the Spice deck for delay measurement between TRIGGER_PIN and TARGET_PIN, and slew measurement at TARGET_PIN.
<code>-use_ndw_for_constraint_check {true false}</code>	Enables constraint check deck generation with NDW waveforms.
<code>-use_noise_model_when_cond {true false}</code>	Allows to use the when condition from a pin noise model.
<code>-view string</code>	Specifies the view name, if glitch spice deck is created other than default view.
<code>-waveform_aware_pulse_width_checks {true false}</code>	Generates the Spice deck for waveform-aware pulse width checks.
<code>-xtalk {delay voltage_low_glitch voltage_high_glitch}</code>	Generates the SI SPICE Deck for the stage. A stage can start with a victim driver input to victim receiver input and receiver output. You can specify one of the following options: • delay: Used to dump the SI delay SPICE deck. • voltage_low_glitch and voltage_high_glitch: Specifies the type of glitch (VL or VH) the SPICE deck will be used for. This option must be used for glitch SPICE deck generation.
<code>> filename</code>	Redirects the output to a file.
<code>>> filename</code>	Appends to an output file.

Examples

- The following section in SPICE deck specifies global supplies and transient analysis window time.

```
*-----  
*Command and Options  
*-----

```

- The following section shows the measurement statements for delay and slew.

```
*-----
*Measurement statements
*-----

.MEASURE TRAN Stage_0001_module1/inst_1/clk_DELAY_
module1/inst_1/q -----clk to q delay
+ TRIG V(module1/inst_1/clk) VAL=0.5 TD=167.9p RISE=1 of module1/inst_1
+ TARG V(module1/inst_1/q) VAL=0.5 TD=167.9p RISE=1
.MEASURE TRAN Stage_0001_module1/inst_1/q_SLEW
+ TRIG V(module1/inst_1/q) VAL=0.30 TD=167.9p RISE=1 -----Slew at
+ TARG V(module1/inst_1/q) VAL=0.70 TD=167.9p RISE=1 module1/inst_1/q pin
.MEASURE TRAN Stage_0002_module1/inst_1/q_DELAY_
module1/inst_2/a -----Interconnect Delay
+ TRIG V(module1/inst_1/q) VAL=0.5 TD=167.9p RISE=1 and Input Slew
+ TARG V(module1/inst_2/a) VAL=0.5 TD=167.9p RISE=1
.MEASURE TRAN Stage_0002_module1/inst_2/a_SLEW
+ TRIG V(module1/inst_2/a) VAL=0.30 TD=167.9p RISE=1 -----Interconnect Delay
+ TARG V(module1/inst_2/a) VAL=0.70 TD=167.9p RISE=1 and Input Slew
```

Note: The `DELAY` and `SLEW` keywords in the `MEASURE` statements indicate that these are the measurement statements for delay and slew respectively.

- The following command sets the simulation time stop criteria to be 13.40 ns and step time to be 1ps:

```
tempus > write_spice_deck -monte_carlo_sim_init_args "stop=1.34e-08 step=1p"
```

- The following command writes out statistics block in a deck to run Monte Carlo simulations:

```

System Commands - Basic Tool-Tcl Commands

- [gui_hide](#)
- [gui_show](#)
- [help](#)
- [man](#)
- [tempus](#)

gui_hide

`gui_hide`

Closes the graphical user interface (GUI) for Tempus.

Parameters

<code>-help</code>	Prints out the command usage.
--------------------	-------------------------------

Related Commands

- [gui_show](#)

gui_show

gui_show
[-help]
[on | off]

Opens the Tempus main window. This is usually done after executing the command `Tempus -init tclCommandFile`.

If you run the `gui_show` command when the Tempus main window is already displayed, the form is refreshed and the display is fitted to the design area.

Note: If you started the Tempus software with the `tempus -gui_show off` command, you cannot then use the `gui_show` command to display the Tempus main window.

Parameters

- help	Prints a brief description that includes type and default information for each <code>win</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man gui_show</code>
on off	Specifies to on or off the window.

Related Commands

- `gui_hide`

help

```
help
[-help]
[<pattern1>]
[<pattern2>]
[-category category]
[-detail | -summary ]
[-command | -attribute | -obj | -message ]
```

Displays help information related to a command, object, attribute or message based on the specified arguments.

By default, only commands, objects and attributes are searched for help.

Parameters

- attribute	Searches attributes only.
-category category	Returns only those attributes that are in the given category.
-command	Searches commands only.
-detail	Provides detailed help, even when multiple help strings are returned. By default, a short help description is returned if more than one items are matched.
-message	Searches messages only. Note, By default messages are not searched. This option is required to see the message help.
-obj	Searches objects only.
pattern1	Searches for any command, object, or attribute that matches pattern1. Pattern matching with * and ? is allowed. If the pattern ends in : (e.g. inst:) only objects will be matched. If the pattern starts with . (e.g. .place*) then only attributes will be matched.
pattern2	Returns help only for those attributes that match pattern2 for the objects matching pattern1. For example, the following command will return all attributes that match place* on the inst object. help inst place*
-summary	Provides a short description even for a single match. By default, if only a single item is matched, the full help description is returned.

Examples

- The following command prints the help for any command, object, or attribute that matches "port*". Note that for attributes, the object it is on is shown in ().

```
tempus> help port*
Objects:
port: External logical ports of the design. See pg_ports for power/ground ports

Attributes:
port(bump)      Port attached to the bump
ports(design)   Ports of design. Does not include pg_ports.
ports(root)     Short-cut for [get_db current_design .ports]
```

- The following command shows the help output for the attribute `.base_cell` on the object `inst:`. The `:` and `.chars` in `inst:` and `.base_cell` are optional as they restrict the search to objects and attributes, respectively.

```
tempus> help inst: .base_cell
Attribute: base_cell (on obj_type: inst)
Description: The base_cell of the inst.
category:
default:
is_computed: false
is_settable: true
is_user_defined: false
skip_in_db: true
type: base_cell
```

- The following output shows the help for a single command:

```
tempus 14> help write_metric
Command: write_metric:

Usage: write_metric [-help] [<pattern>] [-format <string>] [-id <string>] [-merge] [-names <string>] {-file <string> | -inline }

-help          # Prints out the command usage
<pattern>      # List of patterns to match metrics (string, optional)
-file <string> # Filename to write (string, optional)
-format <string> # Data format for the return value (string, optional)
-id <string>    # Database ID to output (string, optional)
-inline       # Return the result instead of writing it to a file (bool, optional)
-merge        # Merge the results into an existing file (bool, optional)
-names <string> # List of patterns to match snapshot names (string, optional)
```

- The following command shows the help output for a message.

```
tempus 14> help -message IMPTCM-48
Error/Warning message: IMPTCM-48: "%s" is not a legal option for command "%s". Either the current option or an option prior to it is not specified correctly.
```

man

```
man
command_name | msg_id
```

Displays information for a command or variable from the *Tempus Text Command Reference*, or prints detailed information for a specified message ID. If no manual page is located, man prints an error message.

The man pages for Tempus commands and variables are located in the following directory:

```
<install_dir>/<platform>/share/tempus/man
```

Parameter

command_name	Indicates the name of the text command (or variable) for which the manual information is required.
msg_id	Specifies the unique message ID for which you want to display detailed information. The output is categorized in three sections: - NAME: Displays the message ID and its severity level. - SUMMARY: Displays the summary of the message text. - DESCRIPTION: Displays detailed information about the message. The detailed information can include the background of the message, likely causes, and alternative steps to troubleshoot the problem.

Example

- The following command returns the manual description of the command `report_timing`:

```
man report_timing
```
- The following command returns the manual description of the `ENCSYC-2` message ID:

```
man ENCSYC-2
```

tempus

```
tempus
[-abort_on_error]
[-batch]
[-cds_lib_file in_file]
[-stylus]
[-cpus integer]
[-disable_user_startup]
[-distributed]
[-execute Tcl_commands]
[-files in_file_list]
[-help]
[-lic_multi_cpu lic_list]
[-lic_options lic_list]
[-lic_startup lic_list]
[-lic_startup_options lic_list]
[-log prefix]
[-no_gui]
[-no_logv]
[-overwrite]
[-eco]
[-version]
[-wait minutes]
```

Starts the Tempus software. If you do not specify any parameters, the following actions occur:

- A log file and a command file are created in the form `tempus.log#` and `tempus.cmd#`.
- The first available license is checked out.
- The Tempus main window opens.

Parameters

-help	Prints out the command usage. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man tempus</code>
-abort_on_error	Exits if an error is detected at any point. If any Tcl command returns <code>TCL_ERROR</code> to the top level, or any <code>Error (XXX) : ...</code> message occurs, the process will exit.
-batch	Runs without interactive prompt. After all the options, including <code>-execute</code> and <code>-file</code> , are processed, the job exits.

<code>-cds_lib_file in_file</code>	Loads the specified file instead of the default cds.lib file in the current directory to obtain the names and locations of OpenAccess libraries. The cds.lib file is used to list the OpenAccess library names, and their physical locations.
<code>-stylus</code>	Launches Tempus in Stylus Common UI mode.
<code>-cpus integer</code>	Specifies the number of CPUs to be used for multi-threading on current host. This calls the appropriate Tcl command to set the local CPU count. This happens before any <code>-execute</code> or <code>-file</code> commands are processed. This may require extra multi-CPU licenses to be checked out (see <code>-lic_multi_cpu</code>).
<code>- disable_user_startup</code>	Reads only the init file in the installation hierarchy. Does not read init files in the home or current directory. This option suppresses the default loading from the home and current directory, which can be used to guarantee there are no local over-rides to various project settings. For more information, see "Initialization Files" in the Installation and Startup chapter of the <i>Tempus User Guide</i> for init files that are loaded by default.
<code>-distributed</code>	Starts Tempus in the Distributed Static Timing Analysis (DSTA) mode. DSTA supports all the command-line parameters that are supported by non-distributed Tempus, except for the following parameters: • <code>-cds_lib_file</code> • <code>-no_logv</code> • <code>-no_gui</code> This is because DSTA does not support OA, GUI, and verbose log. When you specify these parameters with <code>tempus -distributed</code>, an error message will be displayed.
<code>-execute Tcl_commands</code>	Specifies the Tcl commands to be executed as a quoted string at startup.
<code>-files in_file_list</code>	Specifies one or more Tcl files to be sourced at startup, after the commands specified using the <code>-execute</code> parameter are processed. You can set the shell environment variable <code>CDS_STYLUS_SOURCE_VERBOSE</code> to 0 if you do not want the source command output to default to verbose.

<pre>-lic_multi_cpu lic_list</pre>	Controls which licenses are to be used for higher multi-CPU usage in priority order from left to right. The allowed license names are: <code>tpsmmp</code>: Tempus Timing Signoff Solution MP <code>tpsl</code>: Tempus Timing Signoff Solution L <code>tpsx1</code>: Tempus Timing Signoff Solution XL Note: For information on licenses, see "Product and Licensing Information".
<pre>-lic_options lic_list</pre>	Specifies the order that extra option licenses should be checked-out if needed. In some cases more than one option license can be used to enable a given feature. You can control which options are allowed to be checked-out, and in what priority (from left to right) when required during the run. The allowed license names are: <code>tpstso</code>: Tempus Timing Signoff Solution TSO <code>tpspi</code>: Tempus Timing Signoff Solution - PI (Power Integrity) Option <code>tpsng</code>: Tempus Timing Signoff Solution Next Generation <code>vtsx1</code>: Voltus IC Power Integrity Solution <code>vtsl</code>: Voltus IC Power Integrity Solution <code>vtxaa</code>: Voltus IC Power Integrity Solution Advanced Analysis GXL Option Option licenses can be checked-out dynamically when a specific Tcl command requires it. This may cause the Tcl script to stall and wait for a license, or to exit if the wait period expires. For example, <code>-lic_options "tpstso tpsx1"</code> will only allow these two options to be checked-out dynamically, and in the given priority order. Note: For information, see "Product and Licensing Information".
<pre>-lic_startup lic_list</pre>	Requests one of these base licenses at startup in priority order from left to right. The supported licenses are: <code>tpsl</code>: Tempus Timing Signoff Solution L <code>tpsx1</code>: Tempus Timing Signoff Solution XL <code>vdsp</code>: Virtuoso Digital Signoff Power Solution For example, <code>-lic_startup "tpsx1 tpsl"</code> will try to check-out <code>tpsx1</code> first and then <code>tpsl</code>. The check-outs will be attempted repeatedly until it succeeds or the specified wait (<code>-wait</code>) period expires.

`-lic_startup_options`
`lic_list`

Specifies additional option licenses needed at startup. If not provided, they will be checked out when needed during the run. The allowed license names are:

`tpstso`: Tempus Timing Signoff Solution TSO

`tpspi`: Tempus Timing Signoff Solution - PI (Power Integrity) Option

`tpsng`: Tempus Timing Signoff Solution Next Generation

`vtssl`: Voltus IC Power Integrity Solution

`vtssl`: Voltus IC Power Integrity Solution

`vttaa`: Voltus IC Power Integrity Solution Advanced Analysis GXL Option

For example, `-lic_startup_options "tpsl, tpsxl"` will try to check-out both `tpsl` and `tpsxl` when Tempus starts up. The check-outs will be attempted repeatedly until it succeeds or the `-wait` period expires.

<code>-log prefix</code>	Specifies the prefix for the <code>.log</code>, <code>.cmd</code>, and <code>.logv</code> files. If three arguments are given, such as <code>-log "a b c"</code>, then the three names are used exactly without any extension added. So, <code>-log "mylog mycmd mylogv"</code> will result in <code>mylog mycmd mylogv</code> files. The default for <i>prefix</i> is <code>tempus</code>. So if <code>-log</code> is not specified, <code>tempus.log</code>, <code>tempus.cmd</code>, and <code>tempus.logv</code> files will be created. If you specify <code>-log test</code>, the tool creates <code>test.log</code>, <code>test.cmd</code> and <code>test.logv</code> files. The <code>.log</code> file contains the normal logging output, the <code>.cmd</code> file contains the Tcl commands that were executed, and the <code>.logv</code> file contains a super-set of the <code>.log</code> output plus "verbose" debugging output that is needed only for detailed debugging. If the <code>.log</code> file already exists, an integer is added to the end of all the files to make them unique. This means if <code>-log test</code> is specified, the tool will create <code>test.log test.cmd test.logv</code> for the first run, <code>test.log1 test.cmd1 test.logv1</code> for the next run, and so on. Only the existence of <code>.log</code> is checked, the existence of the <code>.cmd</code> or <code>.logv</code> files is not checked. The <code>-overwrite</code> option can be used to disable this behavior and overwrite an existing <code>.log</code> file. If the prefix has a period in it, the last extension is stripped off for the <code>.cmd</code> and <code>.logv</code> usage. For example, <code>-log out.log</code> will result in <code>out.log out.cmd out.logv</code> files, and <code>-log out.a.log</code> will result in <code>out.a.log out.a.cmd out.a.logv</code> files. You can disable any given file by using <code>/dev/null</code>. For example, <code>-log "my.log /dev/null /dev/null"</code> will only create <code>my.log</code>. <i>Default:</i> <code>tempus.log</code> Note: If you provide the log file name under a directory path and the directory path does not exist, Tempus will create the directory path and save the log file under the directory.
<code>-no_gui</code>	The GUI and Tk are not initialized at startup so only the user type-in window (e.g., xterm) is visible. You can start the GUI later in the session with the <code>gui_show</code> command.
<code>-no_logv</code>	Specifies that verbose log file will not be created.
<code>-overwrite</code>	Overwrites an existing <code>.log</code> file (and associated <code>.cmd</code> and <code>.logv</code> files) instead of adding an integer to make the files unique.

<code>-eco</code>	Needed for running the Timing Signoff Optimization flow <code>eco_opt_design</code> to load the power data from the .lib files at startup. By default, Tempus will not load the power data in .lib files to reduce memory usage, but the Timing Signoff ECO command <code>eco_opt_design</code> needs the power data to run properly.
<code>-version</code>	Returns the program version information.
<code>-wait <i>minutes</i></code>	Specifies the number of minutes the system waits for a license to become available before exiting. <i>Default:</i> 0 (no wait time) <i>Value Range:</i> 0 to 10,000

Initialization Files

By default, various initialization files are loaded at startup, if they exist. They can be used to configure the GUI, load utility Tcl files, or configure Tempus settings. The initialization files are read in the following order:

1. `~/ { .enc.pref.tcl, .enc.color.tcl }` in the home directory if the GUI is enabled
2. `./ { enc.pref.tcl, enc.color.tcl }` in the current directory if the GUI is enabled
3. `~/ .enc` in the home directory
4. `<install_dir>/etc/tempus/enc.tcl` in the installation directory
5. `~/ enc.tcl` in the home directory
6. `./ enc.tcl` in the current directory

If the `-stylus` parameter is specified, the initialization files are loaded in the following order instead:

1. `~/ .cadence/tempus/ { gui.pref.tcl, gui.color.tcl, workspaces }` in the home directory if the GUI is enabled
2. `.cadence/tempus/ { gui.pref.tcl, gui.color.tcl, workspaces/ }` in the current directory if the GUI is enabled
3. `<install_dir>/etc/tempus/tempus.tcl` in the installation directory
4. `~/ .cadence/tempus/tempus.tcl` in the home directory
5. `./ .cadence/tempus/tempus.tcl` in the current directory
6. `./ tempus_startup.tcl` in the current directory

Setting Up the Run Time Environment

If `install_dir` is the location of the Tempus installation, then you should setup the run time environment as follows:

- Add the `install_dir/bin` directory to the path. The `bin` directory has links to all the public executable files in the install hierarchy.
- If you want the Stylus Common UI Tempus man pages to be available with the Unix `man` command, then you can add the `install_dir/share/tempus/stylus/man` to your `MANPATH` envvar.
- If you want the Tcl man pages to be available with the Unix `man` command, then you can add the `install_dir/share/tcltools/man` to the `MANPATH` envvar.

For example, you can add the following to the startup shell script:

```
set install_dir = /tools/tempus16.2/lxx86
set path = ($install_dir/bin $path)
setenv MANPATH $install_dir/share/tempus/stylus/man:$install_dir/share/tcltools/man:$MANPATH
```

Note: When Tempus launches, it automatically adds the legacy or the Stylus man pages (when `-stylus` option is specified), and the Tcl man pages at the beginning of the current `MANPATH` inside Tempus. Therefore, from within Tempus the `man` command will show both the sets of man pages before any other man pages.

Temporary File Locations

Each Tempus session creates its own temporary directory to store temporary files at the beginning of the run.

By default, the `tmp_dir` is created in the `/tmp` directory. If the Unix envvar `TMPDIR` is set, then the `tmp_dir` is created inside `$TMPDIR`.

The name of the `tmp_dir` will appear as given below:

```
tempus_temp_[pid]_[hostname]_[user]_xxxxxx
```

Where `_xxxxxx` is a string that is added to make the directory unique. For example:

```
tempus_temp_10233_farm254_bob_nfp9ez
```

The temporary directory is automatically removed on exit or if the run is terminated with a catchable signal (e.g., `SIGSEGV`).

Examples

- The following command starts the Tempus software with log file named myLog.log and command log file named myCmdLog.log:

```
tempus -log myLog.log -cmd myCmdLog.log
```

- The following command starts Tempus, and enables the Tempus Signoff Optimization (TSO) feature of the software:

```
tempus -eco
```

Tempus ECO Commands and Attributes

- [opt_signoff](#)
- [opt_signoff Category Attributes](#)
- [read_hierarchical_def](#)
- [read_partition](#)
- [write_eco_opt_db](#)

opt_signoff

```
opt_signoff  
[-help]  
[-area]  
[-drv]  
[-dynamic]  
[-hold]  
[-leakage]  
[-power]  
[-setup]  
[-update_timing]
```

Triggers ECO. Depending on the `opt_signoff` category attributes settings, it will either auto generate the ECO Timing DB or load existing one, then proceed to the timing fixing phase and finally output an ECO file and detailed diagnostics in log file.

Note: This command requires a 64-bit executable.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>opt_signoff</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man opt_signoff</code>.
-area	Reclaims area on the netlist without causing any DRV/Setup/Hold degradation.
-drv	Optimizes DRV violations. DRV optimization fixes violations in the following order: 1. glitch 2. drv (max_transition/max_capacitance violations) 3. xtalk delta delay Note: • DRV optimization supports buffer addition and resizing. • CelIEM violations are fixed only when <code>set_db opt_signoff_fix_cell_em</code> is set to <code>true</code>.
-dynamic	Prints initial and final power numbers. It optimizes the dynamic power to reduce the total power consumption.
-hold	Optimizes hold violations.
-leakage	Optimizes leakage power. Leakage optimization supports VT swapping.
-power	Optimizes total power in the design. During total power optimization, the software performs swapping and sizing on both the combinational and sequential cells, and also do buffer removal when enabled. It reduces leakage, internal, and switching power in the design.
-setup	Optimizes setup timing violations. Setup optimization supports buffer addition, VT swapping and resizing.
-update_timing	Generates the updated timing data to be used during optimization. Note: This parameter is applicable only for the Tempus Paradime flow or Certus. It is only valid if <code>opt_signoff_allow_multiple_incremental</code> is <code>true</code>.

Examples

- The following commands are used to annotate the parasitics of three active RC corners in the design using SPEF files before running timing analysis or `opt_signoff`:

```
tempus> read_spef -rc_corner rc_max max.spef.gz
tempus> read_spef -rc_corner rc_min1 min1.spef.gz
tempus> read_spef -rc_corner rc_min2 min2.spef.gz
```

- The following command performs hold fixing while not degrading setup timing:

```
tempus> opt_signoff -hold
```

- The following command recovers area by performing cell downsizing and buffer deletion while ensuring not to create any new Setup/Hold/DRV violations.

```
tempus> opt_signoff -area
```

- The following command runs multiple types of optimization in incremental mode and generates new ECO DB (assuming `opt_signoff_read_eco_opt_db` is not used). It also generates the new timing data to be used during power and setup optimizations.

```
set_db opt_signoff_allow_multiple_incremental true
opt_signoff -drv
opt_signoff -setup
opt_signoff -hold
opt_signoff -power -update_timing
opt_signoff -setup -update_timing
```

- `opt_signoff_verbose`
- `opt_signoff_write_eco_opt_db`

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `opt_signoff` category, use the following command:

```
get_db -category opt_signoff
```

opt_signoff_add_inst

```
opt_signoff_add_inst {true | false}
```

Default: true

Data_type: Boolean

Specifies whether or not Setup/Hold/DRV optimizer is allowed to add buffer/delay/swap cell instances.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_add_load

```
opt_signoff_add_load {true | false}
```

Default: false

Data_type: Boolean

Specifies whether Hold optimizer is allowed to add dummy cell instances.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_allow_multiple_incremental

```
opt_signoff_allow_multiple_incremental {true | false}
```

Default: false

Data_type: Boolean

Allows to run multiple types of optimization in incremental mode. Note that there should not be any `report_*` commands between successive `opt_signoff` commands. The recommended order to fix violations is DRV, Hold, and Setup. Hold and Setup can be interchanged but DRV optimization must be performed first. You must specify a unique ECO file prefix before each optimization step. You can then source all the ECO files in the same order as these were generated to run the What-If analysis later.

Note:

If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_allow_skewing

`opt_signoff_allow_skewing {true | false}`

Default: false

Data_type: Boolean

Allows clock skewing to be done during Setup timing optimization to further improve Setup slack. When set to `true`, `opt_signoff -setup` works on any level of the clock tree to modify the clock skew in order to improve Setup timing closure. Modification on the clock tree can be either resizing of the last level of the clock tree or buffering to pad the endpoint clock pin.

Note:

- If set, this parameter must be applied before `opt_signoff`.
- When `opt_signoff_allow_skewing` is active, `opt_signoff` will automatically unfix all clock tree instances/nets. This is also performed when implementing the ECOs.
- As for data path optimization, skewing is not allowed to create new Hold-violated paths.
- When HC-ECO (High Capacity ECO) is enabled, the `opt_signoff_allow_skewing true` setting must be set before the design is loaded (that is, before the `distribute_read_db` command).

Related Commands

- `opt_signoff`

opt_signoff_along_route_buffering

`opt_signoff_along_route_buffering {true | false}`

Default: true

Data_type: Boolean

When set to 1, the software uses node location provided through the parasitic data in order to insert buffers along the routing topology not only at the start or end of the net. This helps to better balance the slew or the load for long nets, which is typically needed for setup timing optimization or DRV fixing.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_buffer_cell_list

`opt_signoff_buffer_cell_list cell_list`

Default: ""

Data_type: String

Specifies a list of buffer/delay cells that can be used for the timing optimizer, regardless of whether those cells have a dontUse attribute. When the list is empty, the software will automatically identify the list of usable buffer/delay cells.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_check_type

`opt_signoff_check_type {early | late | both}`

Default: both

Data_type: Enum

Specifies the check type for path based analysis.

Note: If set, this attribute must be applied before `write_eco_opt_db`.

Related Commands

- `opt_signoff`

opt_signoff_clock_cell_list

`opt_signoff_clock_cell_list cell_list`

Default: " "

Data_type: String

Restricts the list of buffers/inverters/gating or any other cells that are allowed to be used by ECO on the

clock tree.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_clock_max_level`

`opt_signoff_clock_max_level integer`

Default: 0

Data_type: Integer

Specifies the maximum levels in clock skewing thus limiting the amount of clock tree levels and avoiding the creation of an unbalanced clock tree. This attribute sets an upper boundary when adding a buffer or pair of inverters to the clock nets. The software counts the number of levels in the clock tree branch that is being modified to ensure that the maximum level will be equal to or less than the value set by this attribute.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_create_smart_mmmc_db`

`opt_signoff_create_smart_mmmc_db {true | false}`

Default: false

Data_type: Boolean

Enables saving the additional compact timing information in the ECO DB directory during the STA session. When set to `true`, the attribute must be applied before the `write_eco_opt_db` command and has no effect on the `opt_signoff` command.

Related Commands

- `opt_signoff`

opt_signoff_delete_inst

```
opt_signoff_delete_inst {true | false}
```

Default: true

Data_type: Boolean

Enables buffer deletion when doing timing, power, or area reduction. This option is not honored by the `-leakage` parameter of `opt_signoff` since it performs only swapping.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_disable_geometry_checks

```
opt_signoff_disable_geometry_checks {true | false}
```

Default: false

Data_type: Boolean

Performs Vth swapping without checking the cell pins and geometry. Skipping the geometry checks during Vth swapping allows the software to only check the cell size while performing Vth swapping. This will lead to more Vth swaps. However, if you use this attribute, ecoRouting will need to be done once the ECOs are applied since the pin geometries between old and new cells might not match.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_dont_touch_partition_list

```
opt_signoff_dont_touch_partition_list string
```

Default: ""

Data_type: String

Selects a list of partition module names not to be touched during optimization(s). For paths that traverse across the specified hierarchies, optimization would only be applied to a portion of the paths that lie on the non-dont_touch side.

Notes:

- This parameter is exclusive to `opt_signoff_touch_partition_list`.
- This parameter must be applied before `opt_signoff` and can be changed between each call of `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_drv_margin`

`opt_signoff_drv_margin value`

Default: 0.0

Data_type: Integer

Specifies a margin value by which ratio the DRV check will be relaxed or tightened.

Note:

- The software only accepts values from -0.7 to +0.7. A positive value indicates tighter constraints.
- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_eco_file_prefix`

`opt_signoff_eco_file_prefix prefix`

Default: " "

Data_type: String

Specifies the prefix name for the ECO files that are generated.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_em_type

```
opt_signoff_em_type {avg | peak | rms | all}
```

Default: all

Data_type: Enum

Fixes the electromigration (EM) type during DRV optimization in standalone Tempus ECO. You can specify any one of the following options:

- **avg:** Specifies the average current limit violations.
- **peak:** Specifies the peak current limit violations.
- **rms:** Specifies the Root-Mean-Square (RMS) current limit violations.
- **all:** Specifies the worst of the avg/peak/rms violations.

Related Commands

- `opt_signoff`

opt_signoff_enable_high_capacity_eco

```
opt_signoff_enable_high_capacity_eco {true | false}
```

Default: false

Data_type: Boolean

Enables database size reduction on the manager session for high capacity ECO timing/power closure, based on timing violations, list of partition name, or user-defined path_group. You must apply this parameter before the `write_eco_opt_db` command, whereas it is not required during the ECO fixing session. Note that in the Tempus Paradime flow or Certus, this parameter is replaced by `set_distribute_mmmc_mode -enable_high_capacity_eco`, and is set before `distribute_read_db`.

Related Commands

- `opt_signoff`

opt_signoff_fix_cell_em

```
opt_signoff_fix_cell_em {true | false}
```

Default: false

Data_type: Boolean

Fixes the cell level signal electromigration violations during DRV fixing using resizing and additional transforming techniques.

Note:

- If set, this parameter must be applied before `opt_signoff -drv`.
- If set during DRV fixing, the tool will fix only the cell EM violations. This implies that fixing of `max_transition/max_capacitance/SI glitch/SI Xtalk/IR drop` will be disabled.

Related Commands

- `opt_signoff`

opt_signoff_fix_clock_drv

`opt_signoff_fix_clock_drv`

Default: `false`

Data_type: Boolean

Fixes `max_cap/max_tran` violations on clock nets.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_fix_data_drv

`opt_signoff_fix_data_drv`

Default: `true`

Data_type: Boolean

Fixes `max_cap/max_tran` violations on the data networks. This is performed only when the `opt_signoff -drv` command is run.

Related Commands

- `opt_signoff`

opt_signoff_fix_glitch

```
opt_signoff_fix_glitch {true | false}
```

Default: false

Data_type: Boolean

Performs SI glitch fixing during DRV fixing using resizing and buffering techniques.

Notes:

- This attribute must be set during ECO DB generation.
- The glitch fixing is done before max_tran/max_cap fixing.
- If set, this attribute must be applied before `write_eco_opt_db`.

Related Commands

- `opt_signoff`

opt_signoff_fix_hold_allow_setup_degrade

```
opt_signoff_fix_hold_allow_setup_degrade {none | low | medium}
```

Default: none

Data_type: Enum

Guides the Hold fixing engine to determine the effort it has to put to resolve timing violations, and how much flexibility it has to impact the Setup timing.

- When set to `low`, the Hold optimization engine will buffer sink pins that have large Setup positive slack even though the net Setup slack is hardly meeting timing.
- When set to `medium`, the Hold optimization engine will behave the same as in the `low` mode but will also allow Setup TNS to degrade, if required.

Note:

- This attribute is honored by the Hold optimization engine.
- If set, this attribute must be applied before `opt_signoff`.
- When `opt_signoff_fix_hold_allow_setup_degrade` is set to `low` or `medium`, the `opt_signoff_fix_hold_allow_setup_tns_degrade` attribute is ignored.

Related Commands

- `opt_signoff`

opt_signoff_fix_hold_allow_setup_optimization

`opt_signoff_fix_hold_allow_setup_optimization {true | false}`

Default: false

Data_type: Boolean

When set to `true`, incremental Setup fixing is performed during Hold fixing in order to create more Setup margins on Hold violated nodes that could not be fixed earlier due to Setup timing conflict.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_fix_hold_allow_setup_tns_degrade

`opt_signoff_fix_hold_allow_setup_tns_degrade {true | false}`

Default: false

Data_type: Boolean

When specified, the Setup Total Negative Slack can be degraded during Hold time violations fixing while still maintaining the Setup Worst Negative Slack in every Setup active views.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_fix_hold_with_margin

`opt_signoff_fix_hold_with_margin value`

Default: 0.0

Data_type: Double

Specifies a slack margin value in nanoseconds for Hold time violations fixing. The purpose is to overfix

any Hold violations by the amount of the margin value. This margin is not applied on nets that are already meeting the Hold target slack.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_fix_hold_variation_aware`

```
opt_signoff_fix_ir_drop {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, more sizing and Vth swapping is performed during Hold fixing in order to reduce the cost of buffer insertion. This is particularly effective when the Hold timing paths have incremental delay due to SI or large SOCV impacted instances.

Note:

- This attribute is only honored by `opt_signoff -hold`.
- If set, this attribute must be applied before `opt_signoff`.

`opt_signoff_fix_ir_drop`

```
opt_signoff_fix_ir_drop {true | false}
```

Default: false

Data_type: Boolean

Fixes the IR drop voltages for all instances in the design.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_fix_max_cap`

```
opt_signoff_fix_max_cap {true | false}
```

Default: `true`

Data_type: Boolean

Specifies that nets with `max_cap` violations should be fixed.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_fix_max_transition`

```
opt_signoff_fix_max_transition {true | false}
```

Default: `true`

Data_type: Boolean

Specifies that nets with `max_tran` violations should be fixed during DRV optimization.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_fix_osus_glitch`

```
opt_signoff_fix_osus_glitch {true | false}
```

Default: `false`

Data_type: Boolean

Fixes nets with overshoot and undershoot glitches during DRV optimization.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_fix_si_slew

```
opt_signoff_fix_si_slew {true | false}
```

Default: false

Data_type: Boolean

Reports signal integrity (SI) slews violations and fixed during DRV optimization. This is run as the first step of optimization before proceeding for any other incremental optimization.

This attribute must be set during ECO DB generation.

Note: If set, this attribute must be applied before `write_eco_opt_db` and `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_fix_slack_in_range_lower_limit

```
opt_signoff_fix_slack_in_range_lower_limit
```

Default: -1e+30

Data_type: Double

Sets the lower slack limit for a violated path to be considered during timing closure.

Related Commands

- `opt_signoff`

opt_signoff_fix_slack_in_range_upper_limit

```
opt_signoff_fix_slack_in_range_upper_limit
```

Default: 1e+30

Data_type: Double

Sets the upper slack limit for a violated path to be considered during timing closure.

Related Commands

- `opt_signoff`

opt_signoff_fix_xtalk

```
opt_signoff_fix_talk {true | false}
```

Default: false

Data_type: Boolean

Reduces the crosstalk on the net that violates the thresholds set by you.

Note: If set, this attribute must be applied before `write_eco_opt_db` and `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_fix_xtalk_preserve_hold

```
opt_signoff_fix_talk_preserve_hold {true | false}
```

Default: false

Data_type: Boolean

When this attribute is set to `true`, the Xtalk fixing engine is not allowed to degrade Hold timing.

Note:

- This attribute is only honored by `opt_signoff -drv` when Xtalk fixing is enabled.
- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_fix_xtalk_preserve_setup

```
opt_signoff_fix_talk_preserve_setup {true | false}
```

Default: false

Data_type: Boolean

When this attribute is set to `true`, the Xtalk fixing engine is not allowed to degrade Setup timing.

Note:

- This attribute is only honored by `opt_signoff -drv` when Xtalk fixing is enabled.

- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_high_effort_cell_list`

`opt_signoff_high_effort_cell_list` *list of cells*

Default: " "

Data_type: String

Enables the controlled utilization of high-leakage or high-power cells during signoff optimization. These cells are typically classified as `dont_use` or `dont_touch` due to their power characteristics; however, they may be beneficial in specific scenarios. When this attribute is specified, ensure that the `don't_use` constraint is set to `false` for cells included in `opt_signoff_high_effort_cell_list`.

- In setup timing optimization, the cells are considered only if they are essential to meet timing requirements without causing a significant increase in power consumption.
- In power optimization, the cells may be inserted if their usage leads to an overall decrease in power usage, such as enhancements in fanin/fanout cone.

This attribute permits considering the specified cells as high-effort resources, using them only when necessary to enhance timing or power efficiency, while maintaining the broader design objective of reducing power impact.

Related Commands

- `opt_signoff`

`opt_signoff_hold_target_slack`

`opt_signoff_hold_target_slack` *value*

Default: 0.0

Data_type: Double

Specifies a target slack value in nanoseconds for hold timing optimize.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_hold_target_slack_per_view`

```
opt_signoff_hold_target_slack_per_view {viewName1 slack1 viewName2 slack2 ... }
```

Default: " "

Data_type: String

When enabled, this attribute allows to force a specific hold target slack per view. If a given Hold active view is not listed in this attribute, the software will use the global Hold target slack set by the `opt_signoff_hold_target_slack` attribute for that view.

Note:

- This attribute is honored by Setup, Hold, Area, Power, and Leakage optimization engines.
- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_hold_xtalk_delta_threshold`

```
opt_signoff_hold_xtalk_delta_threshold value_in_ns
```

Default: 0.3 ns

Data_type: Double

Fixes the nets with the crosstalk delta delay value equal to or greater than a specified threshold value for hold views.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

`opt_signoff_hold_xtalk_slack_threshold`

```
opt_signoff_hold_xtalk_slack_threshold value_in_ns
```

Default: 1000.0 ns

Data_type: Double

Fixes nets with the slack threshold value equal to or less than a specified threshold value for hold views.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_keep_tmp_files

```
opt_signoff_keep_tmp_files {true | false}
```

Default: false

Data_type: Boolean

Keeps all the temporary files generated by DMMMC and Tempus clients for debugging purposes.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_ignore_drv_checks

```
opt_signoff_ignore_drv_checks {true | false}
```

Default: false

Data_type: Boolean

Specifies that DRV checks should be ignored in setup/hold/area/leakage/dynamic optimization.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_include_hold_path_groups

opt_signoff_include_hold_path_groups

Default: " "

Data_type: String

Allows you to select which path group should be considered for Hold timing during `opt_signoff`. It is set before `write_eco_opt_db`, and also specified before `opt_signoff` in case of a different session.

Related Commands

- `opt_signoff`

opt_signoff_include_setup_path_groups

opt_signoff_include_setup_path_groups

Default: " "

Data_type: String

Allows you to select which path group should be considered for Setup timing during `opt_signoff`. It is set before `write_eco_opt_db`, and also specified before `opt_signoff` in case of a different session.

Related Commands

- `opt_signoff`

opt_signoff_inter_partition

opt_signoff_inter_partition

Default: " "

Data_type: String

Selects a list of partition module names to be optimized for the interface logic of the specified partition. During the High Capacity ECO flow, it will reduce the database having the interface logic of the listed partitions only. Each listed partition is treated separately, thus all from/to paths for each partition are included. This attribute must be applied before `write_eco_opt_db` and `opt_signoff`. In case of the Tempus Paradime flow or Certus, it must be applied before `distribute_read_db`.

Note:

It is mandatory to list the partition name inside the file specified with `opt_signoff_partition_list_file`.

- For High Capacity ECO flow, `opt_signoff_partition_list_file` should be specified before `distribute_read_db`.
- For non-High Capacity ECO flow, `opt_signoff_partition_list_file` should be specified before first optimization.

However, any partition name, which is a part of `opt_signoff_inter_partition` and missing in `opt_signoff_partition_list_file` will result in an error, as shown below:

```
**ERROR: (IMPESO-616): Partition 'ptn_wrapper' is missing in  
opt_signoff_partition_list_file file. Partition specified for inter/intra partition fixing  
should be present in opt_signoff_partition_list_file list as well.
```

In case of Certus, since `opt_signoff_partition_list_file` is not required, the software will use `opt_signoff_distributed_optimization_block_restore_file` to identify the partition names.

Related Commands

- `opt_signoff`

`opt_signoff_inter_partition_exclusive`

`opt_signoff_inter_partition_exclusive`

Default: " "

Data_type: String

Selects a list of partition module pair names to be optimized for the interface logic between the specified partitions. During the High Capacity ECO flow, the tool will reduce the database having the interface logic of the listed partitions pairs only. Each listed partition pair is treated separately, all from/to paths between partition pairs are included.

Notes:

- This parameter must be applied before `write_eco_opt_db` and `opt_signoff`. However, in case of the Tempus Paradime flow or Certus, it must be applied before `distribute_read_db`.
- It is mandatory to list the partition name(s) inside the file specified using the `opt_signoff_partition_list_file` parameter:
 - For High Capacity ECO flow, the `opt_signoff_partition_list_file` parameter must be specified before `distribute_read_db`.
 - For non-High Capacity ECO flow, the `opt_signoff_partition_list_file` parameter must be specified before the first optimization.

However, an error is issued when any partition name, which is a part of `opt_signoff_inter_partition_exclusive` is missing in `opt_signoff_partition_list_file`, as shown

below:

****ERROR: (IMPESO-616):** Partition 'tdsp_core' is missing in `opt_signoff_partition_list_file` file. Partition specified for inter/intra/inter_partition_exclusive partition fixing should be present in `opt_signoff_partition_list_file` list as well.

In case of Certus, since `opt_signoff_partition_list_file` is not required, the software will use `opt_signoff_distributed_optimization_block_restore_file` to identify the partition names.

opt_signoff_intra_partition

`opt_signoff_intra_partition`

Default: " "

Data_type: String

Selects a list of partition module names to be optimized for the core logic of the specified partition. During the High Capacity ECO flow, it will reduce the database having the core logic of the listed partitions only. This attribute must be applied before `write_eco_opt_db` and `opt_signoff`. In case of the Tempus Paradime flow or Certus, it must be applied before `distribute_read_db`.

Note:

It is mandatory to list the partition name inside the file specified with `opt_signoff_partition_list_file`.

- For High Capacity ECO flow, `opt_signoff_partition_list_file` should be specified before `distribute_read_db`.
- For non- High Capacity ECO flow, `opt_signoff_partition_list_file` should be specified before first optimization.

However, any partition name, which is a part of `opt_signoff_intra_partition` and missing in `opt_signoff_partition_list_file` will result in an error :

****ERROR: (IMPESO-616):** Partition 'ptn_wrapper' is missing in `opt_signoff_partition_list_file` file. Partition specified for inter/intra partition fixing should be present in `opt_signoff_partition_list_file` list as well.

In case of Certus, since `opt_signoff_partition_list_file` is not required, the software will use `opt_signoff_distributed_optimization_block_restore_file` to identify the partition names.

Related Commands

- `opt_signoff`

opt_signoff_legal_only

```
opt_signoff_legal_only {true | false}
```

Default: true

Data_type: Boolean

Enables the tool to use the physical data to search for legal location while doing any buffer insertion or instance movement. This ensures that there is no instance overlap at the end of the ECO fixing stage, and after sourcing the ECO file in the implementation tool, you can directly run ECO routing.

When this parameter is set to `false`, `opt_signoff` will not check for legal location although physical data is provided. In this mode, `opt_signoff` behaves in a logical mode flow, which means that physical data will be ignored and this might create an instance overlap and will not check local density while inserting buffers. Also, the routing congestion checks are skipped when this parameter is set to `false`. So it is recommended that you first run ECO fixing in the legal-only mode (which is the default mode) and then, depending on the requirement, you may perform an incremental run by setting `opt_signoff_legal_only` to `false`.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_load_cell_list

```
opt_signoff_load_cell_list cell_list
```

Default: ""

Data_type: String

Specifies the list of load cells to be inserted during Hold fixing, regardless of whether those cells have a `dontUse` attribute.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_max_cap_margin

```
opt_signoff_max_cap_margin cap_margin_value
```

Default: 0.0

Data_type: Double

Minimum value: -10.000000

Maximum value: 0.990000

Specifies the ratio by which the max_cap check should be relaxed or tightened.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_max_local_density

`opt_signoff_max_local_density threshold_value`

Default: -1.0

Data_type: Double

Applies a local placement density threshold that the software will honor during timing optimization. When the local density for a given area has overpassed the threshold, the software stops adding or moving more instances in that local area.

Using the default value, the software will not perform any local placement density checks because by default it is running with `opt_signoff_legal_only true`.

This attribute **accepts values greater than 0**. For example, to allow a maximum local placement density of 98%, set the value to 0.98.

Note:

- This attribute is honored by DRV, Setup, and Hold optimization engines.
- If set, this attribute must be applied before `opt_signoff`.
- The `opt_signoff_max_local_density` (greater than 1) and `opt_signoff_legal_only false` settings can cause some placement in later stages while doing `eco_route`.

Related Commands

- `opt_signoff`

opt_signoff_max_opt_runtime

`opt_signoff_max_opt_runtime integer`

Default: 0

Data_type: Integer

Specifies the timeout period for the timing or power optimization phase after which `opt_signoff` will exit the session. When the value of this attribute is set to a positive value, the software restricts the optimization runtime by that value, specified in minutes. The default value of this attribute is 0. This means that there is no limit for the timeout period. When the timeout period is reached, the software will exit the optimization phase, and displays the Tempus prompt with a stable DB.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_max_paths

`opt_signoff_max_paths integer`

Default: 5000000

Data_type: Integer

Specifies the max paths or points control for path-based analysis.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_max_runtime

`opt_signoff_max_runtime integer`

Default: 0

Data_type: Integer

Specifies the time out period (in minutes) after which `opt_signoff` will exit the session.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_max_slack

`opt_signoff_max_slack value`

Default: 0.0

Data_type: Double

Specifies the maximum slack value to be used during ECO Timing DB generation when using PBA. Setting a positive `opt_signoff_max_slack` value forces the tool to retime positive GBA slack paths so that ECO optimization engine can benefit from an extra PBA Setup slack credit when doing Hold fixing or Power recovery. A positive `opt_signoff_max_slack` value implies larger runtime during ECO Timing DB generation, but tool will retime only as many paths as what is specified through the `opt_signoff_max_paths` attribute.

Note: If set, this attribute must be applied before `write_eco_opt_db`.

Related Commands

- `opt_signoff`

opt_signoff_max_transition_margin

`opt_signoff_max_transition_margin tran_margin_value`

Default: 0.0

Data_type: Double

Minimum value: -10.000000

Maximum value: 0.990000

Specifies the ratio by which the max_tran check should be relaxed or tightened.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_nworst

`opt_signoff_nworst integer`

Default: 50

Data_type: Integer

Specifies the nworst control for path-based analysis.

Note: If set, this attribute must be applied before `write_eco_opt_db`.

Related Commands

- `opt_signoff`

opt_signoff_optimize_core_only

`opt_signoff_optimize_core_only {true | false}`

Default: false

Data_type: Boolean

Performs only reg2reg optimization, when set to `true`.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_optimize_replicated_modules

`opt_signoff_optimize_replicated_modules {true | false}`

Default: false

Data_type: Boolean

Allows the software to perform timing optimization inside replicated hierarchies while generating only one ECO file per sets of clones. The cell names of the replicated hierarchies have to be listed in a file pointed by the `opt_signoff_partition_list_file` attribute.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_optimize_sequential_cells

`opt_signoff_optimize_sequential_cells {true | false}`

Default: `true`

Data_type: Boolean

Allows the software to perform timing optimization for sequential cells.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_partition_list_file

`opt_signoff_partition_list_file filename`

Default: `""`

Data_type: String

Enables the software to select the hierarchical instances that should be treated as partitions. The file specified with this parameter must contain a list of module names of those hierarchical instances. The `opt_signoff` command will generate an ECO file for the top module and the partitions (with relative placement locations for cells). The default ECO files are generated as mentioned below:

`top_eco_tempus.tcl` and `top_eco_innovus.tcl`; `blockA_eco_tempus.tcl` and `blockA_eco_innovus.tcl` and so on.

where the top ECO file contains all ECOs, which is a union of top and partition ECOs.

Notes:

- It is mandatory that the modules that are treated as partitions are of type FENCE.
- To avoid performing ECO in a given partition, you need to apply `dont_touch` attribute on that module.
- To perform top-level buffering only, you need to apply `dont_touch` on all the partitions.
- If set, this parameter must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_path_group_file_name

`opt_signoff_path_group_file_name filename`

Default: ""

Data_type: String

Allows you to pass a TCL file, which will be sourced on each Tempus client, after they loaded their respective saved session, which contains the path group definitions to be used by the tool when running in the High Capacity ECO mode. Those path groups can then be referred to `set_db`

`opt_signoff_include_setup_path_groups` and `set_db opt_signoff_include_hold_path_groups` applied on the manager session.

Note: This parameter is only applicable for the Tempus Paradime flow or Certus, and must be specified before `distribute_read_db`.

Related Commands

- `opt_signoff`

opt_signoff_pba_effort

`opt_signoff_pba_effort {medium | high}`

Default: high

Data_type: Enum

When high effort mode is specified, all the optimization engines will perform more aggressive timing closure or area/power recovery with respect to path-based (PBA) timing.

Note: If set, this attribute must be applied before `write_eco_opt_db` and `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_post_mask

`opt_signoff_post_mask {true | false}`

Default: `false`

Data_type: Boolean

Enables the timing closure engine to perform the following netlist changes without touching the base layer mask:

- Inserts the Gate Array buffers or an inverter pair in place of existing Gate Array filler cells.
- Resizes regular cells to Gate Array cells. It also resize Gate Array cells to Gate Array cells.
- Deletes a regular cell.

The software automatically identifies the Gate Array cells by checking which library instances have the same SITE name as the Gate Array filler cells specified by the user. Here, empty spaces will be filled up by the Gate Array filler cells to ensure 100% placement density.

Note:

- This is supported by DRV, Setup, and Hold fixing.
- When `set_db add_tieoffs_cells {{<tieLo_name> <tieHi_name>}}` setting is used, the Metal ECO flow will insert the TieLo cells to connect dangling input pins, in case the existing TieLo cells in the floorplan are extremely far or too overloaded.

Related Commands

- `opt_signoff`

opt_signoff_power_opt_focus

```
opt_signoff_power_opt_focus {total | leakage | dynamic | leakageOnly | dynamicOnly}
```

Default: `total`

Data_type: Enum

Specifies whether a given netlist should be optimized only for leakage or dynamic power reduction, or more for leakage or dynamic power while still reducing the overall total power during total power optimization.

The following options are available:

- `total`: The power optimization engine focuses on getting the optimal total power in the design.
- `leakage`: The power optimization engine optimizes total power but focuses more on leakage power reduction than on dynamic power reduction.
- `dynamic`: The power optimization engine optimizes total power but focuses more on dynamic power reduction than on leakage power reduction.
- `leakageOnly`: The power optimization engine focuses only on leakage power reduction.

- `dynamicOnly`: The power optimization engine focuses only on dynamic power reduction.

Note:

- This attribute is honored by `opt_signoff -power` and also by `opt_signoff -drv/-setup/-hold` when the `opt_signoff_power_aware` attribute is set to `true`.
- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_post_sta_tcl

`opt_signoff_post_sta_tcl filename`

Default: ""

Data_type: String

Specifies the file containing the TCL code that will be executed immediately after signoff timing analysis per view.

Note: If set, this attribute must be applied before `write_eco_opt_db`.

Related Commands

- `opt_signoff`

opt_signoff_power_aware

`opt_signoff_power_aware {true | false}`

Default: false

Data_type: Boolean

Tempus ECO provides the ability to take power as part of the overall cost function when doing timing closure.

When this parameter is enabled before the start of an optimization session, the current optimization and any subsequent optimizations (if running in incremental mode) checks for power changes for all optimizers and transforms during any changes in the design.

In any of the above cases, the first priority remains getting best final timing but enabling this option will get there with possibly slighter ECO although resulting in lesser final power.

For example, while fixing a Setup timing path violation, by default, the tool chooses to size one instance

to a high leakage cell, while with the `-opt_signoff_power_aware` mode, the tool tries to get to same timing by doing multiple sizing to non-high leakage cells.

Note :

- This feature requires power activity to be annotated on the netlist with the `report_power` command, either through external activity file (recommended) or using propagated activity based on some default toggling rate.
- This feature honors the `-opt_signoff_power_opt_focus` parameter, which means that you can decide to force the tool in reducing more the total or leakage or dynamic power increase.

Related Commands

- `opt_signoff`

opt_signoff_pre_sta_tcl

`opt_signoff_pre_sta_tcl filename`

Default: ""

Data_type: Boolean

Specifies the file containing the TCL code that will be executed immediately before signoff timing analysis per view.

Note: If set, this attribute must be applied before `write_eco_opt_db`.

Related Commands

- `opt_signoff`

opt_signoff_prefix

`opt_signoff_prefix prefix`

Default: ESO

Data_type: String

Specifies the prefix to be assigned to the new instances inserted.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_read_eco_opt_db

`opt_signoff_read_eco_opt_db dir_name`

Default: ""

Data_type: String

Specifies the path of directory where previously generated database files are stored.

Related Commands

- `opt_signoff`

opt_signoff_read_irdrop_db

Default: ""

Data_type: String

Specifies the path of the directory where command, `debug_irdrop`, generated IR drop DB files are kept.

Related Commands

- `opt_signoff`

opt_signoff_read_smart_mmmc_db

`opt_signoff_read_smart_mmmc_db <dirName>`

Default: ""

Data_type: String

Points Tempus ECO to the ECO DB directory containing the additional compact timing information during the ECO fixing session. This attribute must be set before the design is loaded and must point to an ECO DB directory, which was previously generated through `write_eco_opt_db` using the setting, `set_db opt_signoff_create_smart_mmmc_db true`.

Note: Before `opt_signoff`, you still need to point to the ECO DB directory using the setting, `set_db opt_signoff_read_smart_mmmc_db <dirName>`.

Related Commands

- [opt_signoff](#)

opt_signoff_resize_inst

```
opt_signoff_resize_inst {true | false}
```

Default: true

Data_type: Boolean

Enables or disables resizing transform.

Related Commands

- [opt_signoff](#)

opt_signoff_retime

```
opt_signoff_retime {none | aocv | path_slew_propagation | aocv_path_slew_propagation |  
waveform_propagation | aocv_waveform_propagation}
```

Default: path_slew_propagation

Data_type: Enum

Selects the retime mode for path-based analysis.

For more details related to the parameters, see the [report_timing](#) command.

Related Commands

- [opt_signoff](#)

opt_signoff_retime_depth

```
-opt_signoff_retime_depth {default|infinite}
```

Default: default

Data_type: Enum

Retimes depth for exhaustive path-based analysis.

Related Commands

- `opt_signoff`

opt_signoff_retime_depth_early

`-opt_signoff_retime_depth_early {default|infinite}`

Default: default

Data_type: Enum

Retimes depth for exhaustive path-based early analysis.

Related Commands

- `opt_signoff`

opt_signoff_retime_mode

`-opt_signoff_retime_mode {none|path|exhaustive}`

Default: path

Data_type: Enum

Retimes mode for path-based analysis.

Related Commands

- `opt_signoff`

opt_signoff_route_congestion_threshold

`opt_signoff_route_congestion_threshold threshold_value`

Default: 0.7

Data_type: Double

Allows to change the threshold value at which the software considers a local area for routing congestion buffering, to further allow any ECO change. This parameter accepts value between 0 (minimum) and 1 (maximum).

To tighten the routing congestion checks, apply a value between 0 and 0.7. To relax the routing congestion checks, apply a value between 0.7 and 1.

- *Min value:* 0
- *Max value:* 1

Note:

- This parameter is honored by DRV, Setup, Hold, Area, and Power optimization engines.
- If set, this parameter must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_routing_congestion_aware

`opt_signoff_routing_congestion_aware {true | false}`

Default: false

Data_type: Boolean

Checks routing congestion before adding buffers.

Related Commands

- `opt_signoff`

opt_signoff_select_drv_net_file

`opt_signoff_select_drv_net_file {true | false}`

Default: ""

Data_type: String

Specifies a file containing the list of nets to be optimized during DRV fixing. The fixing of max_transition, max_capacitance, SI glitch, SI Xtalk, and SI Slew violations occurs only on the specified nets and the other violating nets are ignored. The file specified includes one net per line.

Note:

- Wild cards and regular expressions are not supported in this file.
- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_select_drv_pin_file

`opt_signoff_select_drv_pin_file`

Default: ""

Data_type: String

Allows you to provide a list of instance pin, which is optimized during `opt_signoff -drv`. It is set before `write_eco_opt_db` for the High Capacity ECO flow, and also specified before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_select_hold_endpoints

`opt_ signoff_select_hold_endpoints` *file_name*

Default: ""

Data_type: String

Specifies a file containing the list of selected endpoints for hold fixing.

Note: When including endpoints, the `opt_signoff_optimize_core_only` attribute must be set to `false`.

File format:

<View> include/exclude <Endpoints>

<View> can be specified as either viewName or V* (if the endpoints are to be included/excluded for all views)

<Endpoints> can be specified in three ways:

- As space-separated list of endpoint names: for example, E1 E2 E3.
- Slack range in nanosecond: <minSlack> <maxSlack>, where all endpoints with the slack greater than or equal to `minSlack` and slack less than or equal to `maxSlack` will be included/excluded, for example, -2.0 -1.0.
- E*, if all endpoints for the view need to be included/excluded.

Related Command

- `opt_signoff`

opt_signoff_select_setup_endpoints

`opt_ signoff_select_setup_endpoints` *file_name*

Default: ""

Data_type: String

Specifies a file containing the list of selected endpoints for setup fixing.

Note: When including endpoints, the `opt_signoff_optimize_core_only` attribute must be set to `false`.

File format:

`<View> include/exclude <Endpoints>`

`<View>` can be specified as either `viewName` or `V*` (if the endpoints are to be included/excluded for all views)

`<Endpoints>` can be specified in three ways:

- As space-separated list of endpoint names: for example, `E1 E2 E3`.
- Slack range in nanosecond: `<minSlack> <maxSlack>`, where all endpoints with the slack greater than or equal to `minSlack` and slack less than or equal to `maxSlack` will be included/excluded, for example, `-2.0 -1.0`.
- `E*`, if all endpoints for the view need to be included/excluded.

Related Command

- `opt_signoff`

opt_signoff_setup_recovery

```
opt_signoff_setup_recovery {true | false}
```

Default: false

Data_type: Boolean

Specifies power-aware setup recovery for setup fixing.

Related Commands

- `opt_signoff`

opt_signoff_setup_target_slack

```
opt_signoff_setup_target_slack slack
```

Default: 0.0

Data_type: Double

Specifies a target slack value in nanoseconds for Setup timing optimization.

Related Commands

- `opt_signoff`

opt_signoff_setup_target_slack_per_view

```
opt_signoff_setup_target_slack_per_view {viewName1 slack1 viewName2 slack2 ... }
```

Default: ""

Data_type: String

When enabled, this attribute allows to force a specific setup target slack per view. If a given Setup active view is not listed in this attribute, the software will use the global Setup target slack set by the `opt_signoff_setup_target_slack` attribute for that view.

Note:

- This attribute is honored by Setup, Hold, Area, Power, and Leakage optimization engines.
- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_setup_xtalk_delta_threshold

`opt_signoff_setup_xtalk_delta_threshold value_in_ns`

Default: 0.3 ns

Data_type: Double

Fixes the nets with the crosstalk delta delay value equal to or greater than a specified threshold value for setup views.

Related Commands

- `opt_signoff`

opt_signoff_setup_xtalk_slack_threshold

`opt_signoff_setup_xtalk_slack_threshold value_in_ns`

Default: 1000.0 ns

Data_type: Double

Fixes the nets with the slack threshold value equal to or less than a specified threshold value for setup views.

Related Commands

- `opt_signoff`

opt_signoff_set_hold_endpoints_margin

`opt_signoff_set_hold_endpoints_margin file_name`

Default: " "

Data_type: String

Specifies endpoint-specific margin for hold fixing.

Related Command

- `opt_signoff`

`opt_signoff_set_setup_endpoints_margin`

`opt_signoff_set_setup_endpoints_margin` *file_name*

Default: " "

Data_type: String

Specifies endpoint-specific margin for setup fixing.

Related Command

- `opt_signoff`

`opt_signoff_skew_core_only`

`opt_signoff_skew_core_only` {true | false}

Default: false

Data_type: Boolean

When set to `true`, it does not allow the skewing engine to skew sequential elements that are part of an IO boundary timing path.

Note:

- This attribute is only honored by `opt_signoff -setup`.
- If set, this attribute must be applied before `opt_signoff`.

Related Command

- `opt_signoff`

`opt_signoff_skip_drv_net_file`

`opt_signoff_skip_drv_net_file` *file_name*

Default: " "

Data_type: String

Specifies a file containing the list of nets to be excluded during DRV fixing. The fixing of max_transition and max_capacitance violations occurs on nets other than specified nets. The file specified includes one net per line.

Note:

- Wild cards and regular expressions are not supported in this file.
- If set, this attribute must be applied before `opt_signoff`.

Related Command

- `opt_signoff`

opt_signoff_smart_mmmc_effort

```
opt_signoff_smart_mmmc_effort {low | medium | high}
```

Default: low

Data_type: Enum

Controls the trade-off between memory or runtime and timing QoR for timing or power ECO closure flow. This means that higher the effort, the lesser memory or runtime but lesser timing QoR while running `opt_signoff`.

- `low`: Is the recommended (default) setting and ensures there is no timing QoR loss.
- `medium`: Reduces memory and runtime significantly with minimal timing QoR loss.
- `high`: Reduces memory and runtime further when compared to the medium mode, but with additional timing QoR loss.

In the `low` effort mode, which is the default and recommended setting, there is no compromise on timing QoR.

The `medium` and `high` effort modes can be used for initial rounds of ECO timing/power ECO closure flow.

Note: This parameter must be set before the design is loaded.

Related Commands

- `opt_signoff`

opt_signoff_smart_mmmc_force_keep_hold_view_list

```
opt_signoff_smart_mmmc_force_keep_hold_view_list <string>
```

Default: " "

Data_type: String

List of hold views, which have to be retained after SmartMMMC view compaction. These views represent the minimum hold views retained by the system, on top of which additional views can be retained.

Related Commands

- `opt_signoff`

`opt_signoff_smart_mmmc_force_keep_setup_view_list`

```
opt_signoff_smart_mmmc_force_keep_setup_view_list <string>
```

Default: " "

Data_type: String

List of setup views, which have to be retained after SmartMMMC view compaction. These views represent the minimum setup views retained by the system, on top of which additional views can be retained.

Related Commands

- `opt_signoff`

`opt_signoff_smart_mmmc_max_view_count`

```
opt_signoff_smart_mmmc_max_view_count {{setup <maxViewCount>} {hold <maxViewCount>} {drv  
<maxViewCount>}}
```

Default: " "

Data_type: String

Allows you to force the software to collect only a given number of views to cover Setup timing, Hold timing, and DRV. It acts as a limit to prevent smartMMMC from selecting more views than what is specified by the user. This attribute is especially useful in combination with `opt_signoff_smart_mmmc_reduce_clients` as it enables a user-defined limit on hardware resources for Tempus clients.

Note:

- This attribute is only honored by Tempus Paradime or Certus, and should be set before design loading.

- When `opt_signoff_smart_mmmc_max_view_count` is specified, `opt_signoff_smart_mmmc_effort_level` is ignored.
- When `opt_signoff_smart_mmmc_max_view_count` is specified, you need to provide `maxViewCount` for each Setup, Hold, and DRV field.
- `maxViewCount` should be equal or greater than 1 for setup and hold but can be 0 for drv only if you do not specify `set_analysis_view -drv` earlier.

Related Commands

- `opt_signoff`

`opt_signoff_smart_mmmc_reduce_clients`

```
opt_signoff_smart_mmmc_reduce_clients {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the SmartMMMC engine evaluates which views should be retained and available on Tempus clients. This helps to reduce the number of Tempus clients started by Tempus Paradime or Certus.

Default: false

Note:

- This attribute is only honored by Tempus Paradime or Certus, and must be set before design loading.
- The Tempus STA sessions must have been saved with `opt_signoff_create_smart_mmmc_db true`.
- SmartMMMC must be enabled through `set_distributed_mmmc_mode -enable_smart_mmmc`.

Related Commands

- `opt_signoff`

`opt_signoff_swap_inst`

```
opt_signoff_swap_inst {true | false}
```

Default: true

Data_type: Boolean

Enables/disables VT swap resizing. The setup/leakage optimizers do not honor this attribute and always perform VT-swapping.

Related Commands

- `opt_signoff`

opt_signoff_post_mask_gate_array_filler_cells

`opt_signoff_post_mask_gate_array_filler_cells {list_of_Gate_Array_filler_cells_name}`

Default: ""

Data_type: String

Enables the software to list all the Gate Array filler cells that can be deleted or inserted back.

Note: This attribute is applicable in the Metal ECO mode only.

Related Commands

- `opt_signoff`

opt_signoff_post_mask_decap_cells

`opt_signoff_post_mask_decap_cells list_of_decap_cells`

Default: ""

Data_type: String

Lists all the programmable decap cells that are allowed to be removed/reinserted in post-mask mode.

Note: This attribute is applicable in the post-mask mode only.

Related Commands

- `opt_signoff`

opt_signoff_post_mask_filler_cells

`opt_signoff_post_mask_filler_cells list_of_filler_cells`

Default: ""

Data_type: String

Lists all the programmable filler cells that are allowed to be removed in post-mask mode.

Note: This attribute is applicable in the post-mask mode only.

Related Commands

- `opt_signoff`

`opt_signoff_post_mask_logic_cells`

`opt_signoff_post_mask_logic_cells list_of_regular_cells`

Default: ""

Data_type: String

Lists all the programmable regular logic/ECO cells that are allowed to be inserted in place of filler/decap cells during optimization in post-mask mode.

Note: This attribute is applicable in the post-mask mode only.

Example:

The following set of commands allow Hold timing closure in post-mask mode using programmable filler cells:

```
set_db opt_signoff_post_mask true
set_db opt_signoff_post_mask_filler_cells {ln10_ecofiller40x ... ln10_ecofiller4x}
set_db opt_signoff_post_mask_logic_cells {ln10_ecofillsgcap40x ... ln10_ecofillsgcap4x}
set_db opt_signoff_post_mask_decap_cells {ln10_ecodlybt01 ln10_ecobuft04 ... ln10_ecoand02 ...
ln10_ecoinv04 ...}
opt_signoff -hold
```

Related Commands

- `opt_signoff`

`opt_signoff_touch_partition_list`

`opt_signoff_touch_partition_list string`

Default: ""

Data_type: String

Selects a list of partition module names to be considered as touch only during optimizations. Any partition that is not specified using this parameter will be considered as don't_touch during optimization.

Notes:

- This parameter is exclusive to `opt_signoff_dont_touch_partition_list`.
- This parameter must be applied before `opt_signoff` and can be changed between each call of `opt_signoff`.

opt_signoff_upsize_in_power_opt

```
opt_signoff_upsize_in_power_opt {true | false}
```

Default: false

Data_type: Boolean

Allows the power optimization engine to perform cell upsizing in order to recover more power.

Note :

- This attribute is only honored by `opt_signoff -power`.
- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`

opt_signoff_verbose

```
opt_signoff_verbose {true | false}
```

Default: false

Data_type: Boolean

Specifies whether the command should output log file reporting with verbosity or not.

Related Commands

- `opt_signoff`

opt_signoff_write_eco_opt_db

```
opt_signoff_write_eco_opt_db dir_name
```

Default: ecoTimingDB

Data_type: String

Specifies a path of directory where generated database files are kept.

Related Commands

- `opt_signoff`

read_hierarchical_def

```
read_hierarchical_def
[-help]
def_files <...>
[-add_blockage]
[-delete_blockages_over_partition_macro]
[-ignore_drcfill]
[-incremental_ilm_def]
[-preserve_shape]
[-rdl_def string]
[-rdl_orient orientation]
[-rdl_placement {x y}]
[-secondary {{suffix def_file_list}...}]
[-skip_pg]
[-skip_fillers]
[-skip_nets]
[-top_cell_orient orientation]
[-top_cell_placement {x y}]
[-top_scope]
[-transform_file string]
[-skip_routing {[pg|signal] [regular|special] [high_layer_routing]}... [-
to_layer routing_layer_name]]
[-use_top_def_die_area]
[-modules <vCell>+ | -hInsts <hInst>+]
```

Merges DEF data from various blocks to a single chip database. The `read_hierarchical_def` command provides the following features:

- Takes the TOP DEF file and a set of block DEF files and merges them into a single chip database.
- The block and TOP Verilog files (or their DEF files) can be specified in any order. However, if there are empty Verilog module stubs of blocks in some of the parent Verilog files, ensure that the parent Verilog files are specified prior to the child Verilog files.
- There is no need to specify the LEF files for the blocks.
- During the course of this command, TOP rows will be cut around the block boundary, and all block rows will be brought back as is.

- Partition definitions are created for each of the assembled block as per the DIE AREA statement in the block DEF.
- The wire at the block boundaries will be stitched with the electrically connected net's wires at the TOP.
- All orientations of blocks are supported for assembly. Repeated blocks are also supported. Non-R0 master is also supported.

Parameters

<code>-help</code>	Outputs a brief description that includes the type and default information for each <code>read_hierarchical_def</code> parameter. For a detailed description of the command and its parameters, use the <code>man</code> command: <code>man read_hierarchical_def</code>
<code>-add_blockage</code>	Specifies that the missing instances from the netlist should be converted into placement blockages.
<code>def_files <...></code>	Specifies DEF files to be merged.
<code>-delete_blockages_over_partition_macro</code>	Deletes the top design placement and routing (both rectangular and rectilinear) blockages overlapping partitions modules.
<code>-hInsts <hInst>+</code>	Specifies the list of hierarchical instances for which physical data needs to be loaded. The tool then reads data from def file(s) associated to the specified hInstance(s).
<code>-ignore_drcfill</code>	Ignores the special routing with DRCFILL shape attribute.
<code>-incremental_ilm_def</code>	Incrementally flatten the ILM def.
<code>-modules <vCell>+</code>	Specifies the list of modules for which physical data needs to be loaded. The tool then reads data only from def file(s) associated to the specified module(s).
<code>-preserve_shape</code>	Preserves the shapes and geometries when the DEF data from various blocks is merged to a single chip database.
<code>-rdl_def string</code>	Specifies RDL def file.

<code>-rdl_orient <i>orientation</i></code>	Specifies orientation for RDL def.
<code>-rdl_placement {<i>x y</i>}</code>	Specifies offset of RDL def.
<code>-secondary {{<i>suffix def_file_list</i>}}...</code>	Specifies the secondary DEF file(s) to load.
<code>-skip_fillers</code>	Skip merging filler and decap cells.
<code>-skip_nets</code>	Skips merging signal nets section.
<code>-skip_pg</code>	Skips merging routing on pg nets.
<code>-skip_routing {[<i>pg signal</i>] [<i>regular special</i>] [<i>high_layer_routing</i>]}</code> ...	Skips merging routing based on the settings specified. This setting can be any combination of the three optional keywords from the following set: • [<i>pg signal</i>]: Specifies the type of the net on which the routing to be skipped. <i>pg</i> - <i>pg net</i>, <i>signal</i> - <i>signal net</i>, <i>both</i> if not specified. • [<i>regular special</i>]: Specifies the type of routing to be skipped. <i>regular</i> - <i>regular routing</i>, <i>special</i> - <i>special routing</i>, <i>both</i> if not specified. • [<i>high_layer_routing</i>]: Specifies that only the routing on high layers to be skipped, where the layers are calculated automatically. If not specified, the routing on all layers are skipped. The layers can be specified with <code>-to_layer</code> parameter. In that case, the routing on the layers from top to the specified layer are skipped. Note: You need to specify the <code>-to_layer</code> parameter explicitly if <i>high_layer_routing</i> is specified in <code>-skip_routing</code>; otherwise, <i>high_layer_routing</i> is not applicable. For example, you can specify multiple sets of arguments to this parameter, as shown below: <pre>-skip_routing {{<i>pg regular</i>} {<i>signal special</i> <i>high_layer_routing</i>}}</pre>
<code>-to_layer <i>routing_layer_name</i></code>	Skips the routing of layers from top to the specified layer (inclusive) when the <i>high_layer_routing</i> option is specified for the <code>-skip_routing</code> parameter.

<code>-top_cell_orient <i>orientation</i></code>	Specifies orientation for topcell.
<code>-top_cell_placement {<i>x y</i>}</code>	Specifies placement for topcell.
<code>-top_scope</code>	Merges routing on top scope nets only.
<code>-transform_file <i>string</i></code>	Reports the final x and y offsets and orientation in the top-level of each LEF block that got replaced by DEF.
<code>-use_top_def_die_area</code>	Enables the use of TOP DEF DIE AREA.

Examples

Below is a sample template script that describes how to run Tempus ECO for DRV/Setup/Hold optimization on a hierarchical design in Stylus mode :

```
set_multi_cpu_usage -local_cpu 16

read_physical -lef {tech.lef stdCell.lef }

read_mmmc viewDefinition_stylus.tcl

read_netlist "top.v.gz blockA.v.gz"

init_design

set_db add_fillers_cells "list_of_filler"

read_hierarchical_def top.def.gz blockA.def.gz

read_spef -rc_corner corner_worst_CMAX "top_CMAX.spef.gz blockA_CMAX.spef.gz"
read_spef -rc_corner corner_worst_RMIN "top_RMIN.spef.gz blockA_RMIN.spef.gz"

set_db delaycal_enable_si true

set_db opt_signoff_partition_list_file partition.txt

set_db opt_signoff_allow_multiple_incremental true

set_db opt_signoff_optimize_replicated_modules true

set_db opt_signoff_read_eco_opt_db ecoTimingDB
```

```
set_db opt_signoff_eco_file_prefix DRV
opt_signoff -drv
set_db opt_signoff_eco_file_prefix SETUP
opt_signoff -setup
set_db opt_signoff_eco_file_prefix HOLD
opt_signoff -hold
```

Related Commands

- [opt_signoff](#)
- [read_spef](#)

read_partition

```
read_partition  
[-help]  
-def <defFile>  
-verilog <vFile>
```

The `read_partition` command allows you to load the Verilog/DEF files for a module that is currently treated as a black box (represented by LEF/LIB). This command is needed for hierarchical designs in order to assemble the top-level database with all the block-level databases. The tool will automatically create a fence for every partition loaded.

Note: It is mandatory that LEF files for every partitions be provided when loading the top-level database.

Parameters

-def	Specifies the DEF file name.
-verilog	Specifies the Verilog file name.

Examples

- The following command assembles the ptn1 block-level database to the top level database already present in the memory.

```
tempus> read_partition -verilog ptn1.v -def ptn1.def
```

Related Commands

- `read_hierarchical_def`

write_eco_opt_db

write_eco_opt_db
[-help]

Saves an ECO Timing DB after performing timing analysis, in a non-distributed mode or in a distributed-MMMC session. In case several views are active at the same time, ECO Timing DB for each of them is saved. The data is saved in the directory pointed by the `opt_signoff_write_eco_opt_db` attribute.

Note: This command requires a 64-bit executable.

Examples

The following command saves an ECO Timing DB in the `mydb` directory.

```
tempus> set_db opt_signoff_write_eco_opt_db mydb  
tempus> write_eco_opt_db
```

check_boundary_model_consistency

check_boundary_model_consistency
[-help]

Performs several checks on loaded models.

When this command is run, the software performs the following checks:

- Global variables and modes set during the boundary model (BM) generation have the same settings in the loading run.
- If a boundary model sub-module is also instantiated outside of the BM, and the BM definition is used for the module.
- The view definition used to generate the BM is consistent with the loading run's view definition. (BM generation views can be a superset.)
- The loading run's active views are all active during the BM generation.
- Constant logic in the BM generation run has the same constants in the loading run.
- Power nets/voltages are consistent between BM generation and BM loading.
- Chip size is consistent between BM generation and BM loading.

A report file is written for each loaded boundary model. The default name of the report is `${auto_file_prefix}<cell_name>_bmodel_check.txt`, written in to the `$auto_file_dir`. You can specify the name of the report file using the `read_boundary_model -report_file` command parameter.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

Related Commands

- `read_boundary_model`

check_ipd_logic

```
check_ipd_logic  
[-help]  
[-outfile <filename>]  
{ [-multi_pd_type <enum> [-verbose ]]}
```

Performs IPD logic checks and reports power domain crossings information based on data and clock path checks.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-multi_pd_type</code> <code><enum></code>	Specifies the type of IPD logic check that needs to be performed. You can specify the following options: • <code>clock_divergence</code>: Enables similar crossings on the divergent clock check. • <code>clock_crossing</code>: Enables multiple PD crossings on clock path checks. • <code>data_crossing</code>: Enables multiple PD crossings on data path checks. • <code>all</code>: Enables all the crossing checks, except <code>cppr_aware</code>. • <code>cppr_aware</code>: Enables checkd for multiple power domains post the common point.
<code>-outfile</code> <code><filename></code>	Specifies the name of the output report file (suffix .rpt) to be generated.
<code>-verbose</code>	Specifies to generate detailed <code>report_timing</code> output for each check with .tcl suffix.

Examples

- The following command reports all the IPD logic checks in the design:
tempus> check_ipd_logic -multi_pd_type all -outfile ipd_logic_check_report -verbose

The output of `ipd_logic_check_report.rpt` is as shown below:

```

check_ldb_version

```
check_ldb_version  
-library string  
[-help]
```

Checks the library database version. If the library version is not updated, the details of missing features and recommendations for recompiling the library database are displayed.

Parameters

-help	Prints out the command usage.
-library <i>string</i>	Specifies the library database (LDB) file whose version is to be printed.

Examples

The following example displays the missing features/recommendations for the library database `cell_w.db`:

```
tempus > check_ldb_version -ldb cell_w.ldb
```

The output is as shown below:

```
LDB file compiled with tool version: v15.20 ((64bit) mm/dd/yyyy 08:40 (Linux 2.6.18-371.el5))  
File Size is xxxxx  
Source Tool: Innovus
```

check_timing

```
check_timing
[-help]

```

Performs a variety of consistency and completeness checks on the timing constraints specified for a design.

The checks include arrival time and external delay (or required time) for each clock in a multiple clock system. In addition, clock connectivity and data connectivity are checked to make sure the clock or data is propagated as expected. Clock gating points are also reported.

Use this command on generic or mapped netlists. The `check_timing` command considers constants applied to a pin while reporting warnings.

 Use the `check_timing` command before using any commands for timing analysis. Warnings are displayed when problems occur. The [Table](#) below lists the `check_timing` warnings. For best results, re-run the `check_timing` command after resolving each warning. Redirecting the output to a file is the quickest run method.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

<pre>-check_only warning_list</pre>	Allows you to specify warning types. For example, the following command lists the specified warnings only: <pre>check_timing -check_only {uncons_endpoint clock_crossing}</pre> This list can also include warnings that are not listed by default. Valid entries in <i>warning_list</i> are: clock_clipping_freq, clock_clipping_gate, clock_crossing, clock_expected, clock_gating_controlling_edge_unknown, clock_gating_no_data, clock_missing_at_sequential_output, clock_not_propagated, clocks_masked_by_another_clock, const_collision, data_check_multiple_reference_signal, data_check_no_reference_signal, ideal_clock_waveform, invalid_pll_configuration, loop, master_clk_edge_not_reaching, missing_clock_groups, missing_drive, multiple_clock, no_drive, no_gen_clock_source, no_input_delay, partial_input_delay, pulse_non-pulse_clock_merge, signal_level, uncons_endpoint, uncons_endpoints_due_to_case_analysis
<pre>-clock_crossing_output_format {summary csv}</pre>	Specifies the format of the clock crossing report to be generated - as a summary or in csv format.
<pre>{> >>} file_name</pre>	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <i>filename</i> parameter must be the last argument in the list. The <i>filename</i> and <i>-tcl_list</i> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the .gz extension to the file name. Default: Report is displayed on standard output without being saved.

<code>-exclude_warnings warning_list</code>	Excludes the specified warning types when generating the report. Use this parameter to exclude any of the warnings included in the report by default. By default, the software includes the following warnings in the report: <code>clock_expected</code>, <code>loop</code>, <code>ideal_clock_waveform</code>, <code>master_clk_edge_not_reaching</code>, <code>partial_input_delay</code>, <code>missing_drive</code>, <code>no_input_delay</code>, <code>no_drive</code>, <code>no_gen_clock_source</code>, <code>uncons_endpoint</code>, <code>uncons_endpoints_due_to_case_analysis</code>. For a complete list of warnings and their descriptions, refer to Table
<code>-include_warnings warning_list</code>	Includes the specified warning types when generating the report. Use this parameter to add any of the warnings not included in the report by default. By default, the software reports all warnings except the following: <code>clock_clipping_gate</code>, <code>const_collision</code>, <code>clock_crossing</code>, <code>clock_not_propagated</code>, <code>missing_drive</code>, <code>multiple_clock</code>, <code>data_check_multiple_reference_signal</code>, <code>data_check_no_reference_signal</code>, <code>clock_gating_no_data</code>, <code>clock_gating_controlling_edge_unknown</code>, <code>clock_missing_at_sequential_output</code>, <code>signal_level</code>, and <code>clocks_masked_by_another_clock</code>. For a complete list of warnings and their descriptions, refer to Table.
<code>port_or_pin_list</code>	Lists pins or ports. For example: <pre>check_timing -verbose [get_ports in*]</pre>
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-type type_list</code>	Limits the checks to the specified type. <i>Default:</i> All check types are reported.

	<code>clock_clipping</code>: Warns when there is a problem with clock gating that can result in clock clipping. Reports the following warnings: • <code>clock_clipping_freq</code> • <code>clock_clipping_gate</code>
	<code>clocks</code>: Reports the following clock warnings: • <code>clock_crossing</code> • <code>clock_expected</code> • <code>clock_not_propagated</code> • <code>ideal_clock_waveform</code> • <code>master_clk_edge_not_reaching</code> • <code>no_gen_clock_source</code>
	<code>clock_gating_inferred</code>: Warns when inferred clock gating checks are not analyzed by the software, even if a clock signal reaches and is used downstream the clock tree. Reports the following warnings. • <code>clock_gating_controlling_edge_unknown</code> • <code>clock_gating_no_data</code>
	<code>constant_collision</code>: Warns when there is a constant collision on a net connected to the pin or if there is a contradiction on a pin. Constant collision occurs when a net is driven simultaneously by conflicting values and a constant contradiction occurs when a constant constraint on a pin conflicts with the driven value.
	<code>endpoints</code>: For output ports, warns if no output delay constraint is applied to the port or if a specific (min/max rise/fall) output delay is missing. It also warns if an output delay constraint is applied with no clock information. For all endpoints (output ports and register data pins), it warns if any incoming signal is unconstrained. Also warns if a clock arrives where clock is not expected, or if multiple signals arrive at an endpoint.

	inputs: Reports the following input delay, arrival time assertion, and drive assertion warnings: • <code>partial_input_delay</code> • <code>missing_drive</code> • <code>no_input_delay</code> • <code>no_drive</code>	
	loops: Warns when a combinational loop is detected. Reports the loop and the arc used to break the loop. The <code>-pin</code> option is ignored in this case. Also reports loops caused by generated clocks.	
<code>-verbose</code>	Gives detailed information about the warnings. When specified, warnings are grouped and sorted by warning type. <i>Default:</i> Gives a summary of how many warnings of each type exists.	
<code>-view</code>	Reports warning(s) that belong to the specified view.	

Command Order

Use this command after setting all the constraints but before optimizing your design or generating any timing reports.

Warning Messages

The following table shows the `check_timing` warning messages.

check_timing Warning Messages

Warning	Description
<code>clock_clipping_gate</code>	Warning: Clock clipping possible due to wrong gate type or wrong trigger for data input.

clock_clipping_freq	Warning: Clock clipping possible due to incompatible clock signal and data signal frequencies.
clock_crossing	Warning: Clock domains interact. Comments: Checks clock interactions between multiple clock domains in the design. When you specify this parameter, the Timing Check Crossing Clocks report shows the interaction of clocks in the design and indicates whether the paths between the clocks are <code>False</code> or <code>Partial False</code>. If a clock launches one or more paths, which are captured by other clocks, the report lists all pairs of crossing clocks. • This includes inferred clock gating with different reference and signal clock. • If a path has been disabled using the <code>set_disable_timing</code> command, crossing clocks on that path are not reported. If all the paths between two clocks are false paths or they are exclusive/asynchronous clocks, the path is marked as <code>False</code>. The false path can be defined on clocks, for example, <code>set_false_path -clock_to CLK</code> or on pins or ports, such as, <code>-through buf1/Y</code>. If only part of paths are set as false paths or exclusive/asynchronous clocks, the path is marked as <code>Partial False</code>.
	• If a false path is defined only for one check type (say, setup), the crossing clocks are marked as <code>Partial False</code> if the simultaneous setup hold mode is set to <code>on</code>. The crossing clocks are marked <code>False</code> if the analysis type is setup and the simultaneous setup hold mode is set to <code>off</code>. • If only one edge (rise/fall) of a particular clock pair has false paths (say, using <code>-clock_fall</code>), then the path is marked as a <code>Partial False</code>.

clock_expected	Warning: Clock not found where clock is expected. Comments: Indicates that no clock signal is defined at the clock pin. See create_clock.
clock_gating_controlling_edge_unknown	Warning: Unknown controlling edge to perform clock gating check. Comments: Reports library cells with complex functions (MUX or AOI) where controlling edge of signal to perform clock gating check cannot be determined automatically. You need to specify correct edge by <code>-high/-low</code> option using the <code>set_clock_gating_check</code> command to resolve such warning. Note: The software does not report this warning when either: • <code>set_disable_clock_gating_check</code> command is applied on such pins, or • global settings to disable clock gating checks are on.
clock_gating_no_data	Warning: No data signal reaching clock gating enable pin Comments: Reports clock gating enable pins where no valid data signal arrives. You need to do either of the following: • specify valid data signal to reach enable pin of clock gating cells, or • remove any path exceptions or disabled checks that blocks valid data signal to reach enable pin Note: The software does not report this warning when either • <code>set_disable_clock_gating_check</code> is applied on such pins, or • global settings to disable clock gating checks are on.

clocks_masked_by_another_clock	Warning: Clock(s) in fanin cone are dropped due to another clock Comments: Reported timing pins on which creation of a regular or a generated clock causes clock(s) in fanins of such pins have been blocked or masked from propagating further. However, for pins having only master clock waveform on the fanin, this warning is not reported. You can use the detailed mode (<code>-verbose</code> option) to report names of all the incoming clock waveforms that have been blocked.
clock_missing_at_sequential_output	Warning: Found latency phase at sequential output on clock tree instead of clock phase Comments: Reports output pins of sequential elements that lie on source clock tree for the generated clocks created downstream and do not have any valid clock phase. This indicates possible missing clock related checks (e.g., clock gating) on downstream clock tree. You can add clocks on this pin or downstream clock tree only if no valid clock exists until downstream generated clock creation point.
clock_not_propagated	Warning: Clock not propagated Comments: Reports ideal clocks reaching the reference pin of a timing check.
const_collision	Warning: Constant collision Comments: See <code>set_case_analysis</code>.
data_check_multiple_reference_signal	Warning: Multiple clocked signals are reaching data check reference pin Comments: Reports on reference pins for non sequential timing check (data check) where more than one reference data arrives.

data_check_no_reference_signal	Warning: No clocked signal is reaching data check reference pin Comments: Reports reference pins for non-sequential timing check (data check) where no valid reference signal (data phase) arrives. You can do one of the following to resolve such warnings: • add valid reference signals to reach at such reference pins • remove path exceptions or disabled arcs that are blocking such reference signals
ideal_clock_waveform	Warning: Clock waveform is ideal. Comments: Reports clocks that are ideal and are not propagated. This warning type is reported by default (unless <code>-exclude_warning</code> or <code>-check_only</code> parameter is specified). You can use the <code>set_propagated_clock</code> command to avoid this warning.
invalid_pll_configuration	Warning: No valid path exists from output pin to feedback pin of PLL. Comments: Shows PLL (phase locked loop) check warnings. These checks allow you to identify and fix issues in the PLL flow.
loop	Warning: Timing loop found in the design Comments: Indicates that there are timing loops in the design. It also includes loops caused by generated clocks.

master_clk_edge_not_reaching	Warning: Master clock edge does not reach the generated clock target. Comments: This warning means that rise/fall latency edge is not reaching to create generated clock root from the master clock. You can verify if the path that is seeing this warning is actually broken, or edge is somewhere disabled earlier on this path. There is a global <code>timing_enable_genclock_edge_based_source_latency</code> that controls how the software chooses generated clock source latency paths. Details of this global can be found at Tempus text command reference.
missing_clock_groups	Warning: Set clock group related checking Comments: Reports any potential issues with the defined clock grouping data.
partial_input_delay	Warning: Indicates that a rise or fall input delay assertion is not applied.
missing_drive	Warning: Missing specific (rise/fall) drive constraint Comments: Either a rise or fall drive constraint is applied and the other one is missing.
multiple_clock	Warning: Multiple clocks are reaching clock reference pin. Comments: Reports clock pins of sequential or clock gating cells where more than one clock waveform arrives. This warning is for information only and the software performs timing analysis with respect to all such clocks.
no_input_delay	Warning: No input delay assertion with or without <code>-clock</code> option specified. Comments: See <code>set_input_delay</code>.
no_drive	Warning: No drive constraint Comments: See <code>set_driving_cell</code> and <code>set_drive</code>.

no_gen_clock_source	Warning: No clock source found for generated clock. Comments: Indicates that the source pin of the clock generated by the <code>create_clock</code> command is not driven by a clock source.
pulse_non-pulse_clock_merge	Warning: Merge of pulse and non-pulse clock paths. Comments: Reports points where a pulse clock and a non-pulse clock merges.
signal_level	Warning: Driver pin voltage value do not match with sink pin voltage level Comments: Reports net driver/receiver pin pairs for which the pin voltage does not match.
uncons_endpoint	Warning: No constrained signal reaching pin. Comments: For output ports: Primary output port has no implicit timing check. Use <code>set_output_delay</code>, <code>set_max_delay</code>, or <code>set_min_delay</code> to create a valid constraint. For register data pins: There is no valid clock reaching the CK pin of the register data pin. Check for missing <code>create_clock</code> for the clock network. The endpoints are reported as unconstrained in both in early and late timing. This does not cover all the cases and scenarios because of which endpoint can become unconstrained. To cover all possible cases, you can use the <code>report_analysis_coverage</code> command.
uncons_endpoints_due_to_case_analysis	Warning: Unconstrained signal arriving at end point due to case analysis Comments: Reports unconstrained endpoints due to case analysis. To enable this warning, you must set the <code>timing_report_check_timing_unconstrained_endpoints_due_to_constants</code> attribute to <code>true</code>.

Examples

Here are some examples.

- Consider the following example:

```
in-----|>-----|>-----out

buf1 buf2
```

The Timing Check Crossing Clocks reports False or Partial False in some of the scenarios given below:

- a) `set_input_delay` with respect to CLK1 on in and `set_output_delay` with respect to CLK2 on out:

```
From Clock      Crossing Clocks
-----
CLK1            CLK2
```

- b) `set_input_delay` with respect to CLK1 on in, `set_output_delay` with respect to CLK2 on out, and `set_false_path -to CLK2` (clock-based false path):

```
From Clock      Crossing Clocks
-----
CLK1            CLK2  (False)
```

- c) If the `set_false_path` becomes `set_false_path -rise_to CLK2`, the following is reported:

```
From Clock      Crossing Clocks
-----
CLK1            CLK2  (Partial False)
```

The following command displays the default summary report:

```
tempus> check_timing
```

```
-----
                        TIMING CHECK SUMMARY
-----
Warning                Warning Description                Number of
```

		Warnings

ideal_clock_waveform	Clock waveform is ideal	1
clock_expected	Clock not found where clock is expected	3
master_clk_edge_not_reaching	Master clock edge does not reach the	
	generated clock target	2
no_drive	No drive assertion	8
no_input_delay	No input delay assertion with respect	
	to clock	4
uncons_endpoint	Unconstrained signal arriving at end point	5

- The following command displays a specified type of warning using the `-type` option if a timing loop is found in the design:

```
tempus> check_timing -type loops
```

TIMING CHECK SUMMARY		

Warning	Warning Description	Number of Warnings

loop	Timing loop found in the design	0

- The following command provides more information about problems and prints a summary using the `-verbose` option:

```
tempus> check_timing -verbose
```

TIMING CHECK SUMMARY		

Warning	Warning Description	Number of Warnings

ideal_clock_waveform	Clock waveform is ideal	1
clock_expected	Clock not found where clock is expected	3

Related Commands

- `report_timing`

check_timing_library

```
check_timing_library  
[-help]  
[-check_power]  
[-lib_cell string]  
[-library string]  
[-out_file string]  
[-report_missing_power_only]
```

Checks the contents of the timing library and reports any inconsistencies in the log file.

You can use the `check_timing_library` command after importing the design and timing libraries.

Parameters

-help	Prints out the command usage.
-check_power	Checks if power constructs, such as, <code>internal_power</code>, <code>leakage_power</code>, or <code>ecsm_power</code>, are defined for the cells. Note: The <code>-check_power</code> parameter is optional. However, if you specify <code>-report_missing_power_only</code>, then you must specify <code>-check_power</code>. If you use the <code>-library</code> parameter, you do not have to specify the <code>-check_power</code> parameter, because when a library-specific cell is given as input, the software automatically checks for power constructs. <i>Default:</i> Only checks if timing is defined for the cells.
-lib_cell <i>string</i>	Specifies the name of the library cell. Note: The <code>-lib_cell</code> parameter is optional. However, if you specify the <code>-library</code> parameter, then you <i>must</i> specify <code>-lib_cell</code>.

<code>-library string</code>	Specifies the timing library in which to check a particular cell. You must specify the <code>-lib_cell</code> parameter with <code>-library</code>, to specify the particular library cell to check. Note: If you use the <code>-library</code> parameter, you do not have to specify the <code>-check_power</code> parameter, because when a library-specific cell is given as input, the software automatically checks for power constructs.
<code>-out_file string</code>	Saves the report output to the specified file.
<code>-report_missing_power_only</code>	Reports only those cells that do not have any defined <code>internal_power</code> (at the pin level), or <code>leakage_power</code>. You must specify the <code>-check_power</code> parameter with the <code>-report_missing_power_only</code> parameter.

Examples

- The following command checks if timing is defined for all cells that have been read into the design, and writes a report to the log file:

```
check_timing_library
```

- The following command checks if timing is defined for all cells that have been read into the design, and writes a report to a file named `CheckTiming1`:

```
check_timing_library -out_file CheckTiming1
```

- The following command checks if timing and power constructs are defined for all cells that have been read into the design, and writes the report to the log file:

```
check_timing_library -check_power
```

- The following command checks if timing and power constructs are defined for all cell that have been read into the design, and writes the report to a file named `CheckTiming2`:

```
check_timing_library -out_file CheckTiming2 -check_power
```

- The following command checks if timing is defined for all cells with the name `A01` in all timing libraries, and writes the report to a file named `CheckTiming3`:

```
check_timing_library -out_file CheckTiming3 -lib_cell A01
```

- The following command checks if timing and power constructs are defined for all cells with the name `A01`, in all timing libraries, and writes the report to a file named `AllA01Check`:

```
check_timing_library -out_file AllA01Check -lib_cell A01 -check_power
```

- The following command checks if timing and power constructs are defined for the cell with the name `A01` in the timing library `minFile1.lib`, and writes the report to a file named `A01Check`:

```
check_timing_library -out_file A01Check -lib_cell A01 -library minFile1.lib
```

Note: When you use the `-library` parameter, you do not have to specify the `-check_power` parameter, because when a library-specific cell is given as input, the software automatically checks for power constructs.

- The following command checks if the `internal_power` and/or `leakage_power` constructs are defined for all cells that have been read into the design, and reports only those cells that do not have the constructs defined. The software writes the report to a file named `MissingPower`:

```
check_timing_library -out_file MissingPower -check_power -report_missing_power_only
```

check_timing_library_consistency

check_timing_library_consistency
[-help]

Checks for missing libraries for instances in the active view.

This command checks whether the library for the cell associated with the instance is present in the associated power domain library set of the instance in the active views.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

Examples

- The following command displays a report showing missing libraries:

```
check_timing_library_consistency
```

The software displays the following information:

```
Checking the Library binding for instance in active view 'vA'
Pass. All instances have library definition in view 'vA'
Checking the Library binding for instance in active view 'vB'
No library found for instance 'U1', cell 'AND2X1', in powerdomain 'PD_BAD', of view 'vB'
Fail. Missing Library for some instance found in view 'vB'
Checking the Library binding for instance in active view 'vAB'
Pass. All instances have library definition in view 'vAB'
```

commit_boundary_model_constraints

commit_boundary_model_constraints
[-help]

Allows the software to pull up a subset of constraints from a block run into the top boundary model session.

When this command is specified, the constraints are applied to instances of a boundary modeled block in a top level boundary model session. For glitch boundary models, glitch constraints, such as, `define_bundled_bus`, `set_glitch_threshold`, `set_cdb_binding`, and `set_quiet_attacker`, are pulled up.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

compare_timing_context

```
compare_timing_context
[-help]
[-abs_thresh float]
[-instances string]
[-module string]
-out_file string
[-pct_thresh float]
-reference string
[-sort_by {abs | pct}]
-target string
[-type {clocks | latency | arrival | required | slew | load | constant | glitch}]
[-verbose]
[-view string]
```

Compares two timing contexts generated by Tempus.

The contents of context like clocks, clock latency, arrival time, required, slew, load, constant, and glitch are compared. To perform context comparison, it is required to generate context using the `-include_text_format` parameter of the `write_timing_context` command.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-abs_thresh float</code>	Specifies the threshold value to compare the context data. The absolute threshold value is specified in pico seconds (ps). <i>Default:</i> 0
<code>-instances string</code>	Specifies the list of instances for which context comparison will be done.
<code>-module string</code>	Specifies the list of modules for which context comparison will be done.
<code>-out_file string</code>	Specifies the output file that will show the differences between reference and target context data.
<code>-pct_thresh float</code>	Specifies the percentage threshold in percent (%). If the difference is greater than both the specified <code>-abs_thresh</code> and <code>-pct_thresh</code> thresholds, the software considers the comparison as “Fail”. <i>Default:</i> 0
<code>-reference string</code>	Specifies the reference path of the context directory.
<code>-sort_by {abs pct}</code>	Sorts the report based on the absolute tolerance or percent tolerance. By default, the report is sorted based on the percentage difference.
<code>-target string</code>	Specifies the name of target context directory used for comparison. Note: The missing entries in target or reference will be represented by “-”.
<code>-type {clocks latency arrival required slew load constant glitch}</code>	Specifies the type of text data to be compared. The <code>latency</code> option includes comparison of the latency, uncertainty, or incremental delay values. By default, all the text data values are compared.
<code>-verbose</code>	Reports the failed as well as passed comparison data.
<code>-view string</code>	Specifies the MMMC analysis view for which context comparison needs to be done.

Context Comparison Report Sections and Examples

The following are the sections of the context comparison report along with examples:

Section 1: Comparison Summary

Shows the summary of total and failed entries/ports in reference and target context comparison. The header contains the view, module, and instance for which the comparison is reported.

```
-----
Top View: view1
Module: Top
Top Instance: inst1
-----

-----
Comparison Summary

prt1 0 1 Fail

Section 4: Detailed Clock Latency Comparison

Provides details of differences in clock latency, pin-based uncertainty, and incremental delays between the reference and target contexts.

Clock Latency Comparison

Port	Clock	Type	Data	Ref	Target	Abs Diff	% Diff	Status
P1	TCK1(P)	latency	early_rise	10.12	10.23	0.11	1.08	Fail
P1	TCK1(P)	incr_delay	early_rise	0.2	0.2	0	0	Pass
P1	TCK1(P)	uncertainty	early_rise	0.1	0.2	0.1	100	Fail
P1	TCK1(P)	latency	late_rise	11.12	11.12	0	0	Pass

Section 5: Detailed Input Arrival Comparison

Provides details of differences in input arrivals between the reference and target contexts.

Input Arrival Comparison

Port	Clock	Data	Ref	Target	Abs Diff	% Diff	Status
test_scanpt	portclk1(P)	early_rise	1206.32	1214.33	8.0017	0.6633	Fail
test_scanpt	portclk0(P)	early_rise	1206.32	1214.33	8.0017	0.6633	Fail
test_scanpt	portclk1(P)	early_fall	1202.58	1210.53	7.9497	0.6610	Fail
test_scanpt	portclk0(P)	early_fall	1202.58	1210.53	7.9497	0.6610	Fail

Section 6: Detailed Required Time Comparison

This section provides the details of differences in required time between the reference and target contexts.

Required Time Comparison

Port	Clock	Data	Ref	Target	Abs Diff	% Diff	Status
tst_scopt	ekph1(P)	early_fall	4.2486	3.2270	-1.0216	-24.0456	Fail
tst_scopt	ekph1(P)	early_rise	-5.9780	-7.0736	-1.0956	18.3272	Fail
tst_scopt	emph1(N)	early_fall	-13.8087	-15.9599	-2.1512	15.5786	Fail
tst_scopt	emph1(N)	early_rise	-23.0335	-25.2794	-2.2459	9.7506	Fail

Section 7: Detailed Input Port Transition Comparison

Provides the details of differences in transition times on input ports between the reference and target contexts.

Input Transition Comparison

Port	Data	Ref	Target	Abs Diff	% Diff	Status
clk2	early_rise	1.510	1.510	0.000	0.000	Pass
clk2	early_fall	0.772	0.772	0.000	0.000	Pass

Section 8: Detailed Output Port Load Comparison

Provides the details of differences in output port load between the reference and target contexts.

Output Load Comparison

Port	Data	Ref	Target	Abs Diff	% Diff	Status
Out	early_rise	171.374	171.374	0.000	0.00	Pass
Out	early_fall	171.374	171.374	0.000	0.000	Pass

Section 9: Detailed Glitch Comparison

Provides the details of differences in glitch value on the pins connected to the input ports between the reference and target contexts.

Glitch Comparison

Port	Pin Name	Data	Ref	Target	Abs Diff	% Diff	Status
clk2	ff3/CK	VH	96.552	96.611	0.059	0.061	Fail
clk2	ff3/CK	VL	95.742	95.776	0.034	0.036	Fail

Related Commands

- `report_timing_context_clock_mapping`

create_analysis_view

```
create_analysis_view
[-help]
-constraint_mode modeName
-delay_corner dcCornerObj
-name viewName
```

Creates an analysis view object that associates a delay calculation corner with a constraint mode. An analysis view object provides all of the information necessary to control a single multi-mode multi-corner analysis.

After creating analysis views, use the `set_analysis_view` command to specify which views to use for setup and hold optimization or timing analysis.

Use this command after creating constraint modes (`create_constraint_mode`) and delay calculation corners (`create_delay_corner`).

Parameters

-help	Prints out the command usage.
-name <i>viewName</i>	Specifies the name of the analysis view being defined.
-constraint_mode <i>modeName</i>	Specifies the name of the constraint mode to associate with this analysis view. A constraint mode groups a set of constraints to be used with any given analysis. To create the constraint mode, use the <code>create_constraint_mode</code> command.
-delay_corner <i>dcCornerObj</i>	Specifies the name of the delay calculation corner object to associate with this analysis view. A delay calculation corner object contains all of the information needed to control delay calculation for a specific analysis view. To create a delay calculation corner, use the <code>create_delay_corner</code> command.

Examples

- The following command creates an analysis view called `missionSlow` using the constraint mode `missionSetup` and the delay calculation corner `dcWCCOM`:

```
tempus> create_analysis_view  
-name missionSlow  
-constraint_mode missionSetup  
-delay_corner dcWCCOM
```

- The following command creates an analysis view called `missionFast` using the constraint mode `missionHold` and the delay calculation corner `dcBCCOM`:

```
tempus> create_analysis_view  
-name missionFast  
-constraint_mode missionHold  
-delay_corner dcBCCOM
```

Related Commands

- `set_analysis_view`
- `create_constraint_mode`
- `create_delay_corner`

create_basic_path_groups

create_basic_path_groups
[-help]
[-expanded]
[-reset]

Explicitly creates standard path groups irrespective of the design stage. The following path groups are created:

- reg2reg (register-to-register)
- reg2cgate (register-to-clock-gate)

Note: If a design does not have any reg2reg paths, or reg2cgate paths, this command will not create the corresponding path group(s).

Parameters

-help	Outputs a brief description that includes type and default information for each <code>create_basic_path_groups</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man create_basic_path_groups</code> .
-expanded	When this parameter is specified, the following path groups are created: • reg2reg • reg2cgate • in2reg • reg2out, and • in2out When this parameter is not specified, only the default path groups, reg2reg and reg2cgate, are created. Note: Timing optimization will consider these path groups in the same way as paths grouped using the <code>group_path</code> command.
-reset	Deletes all existing path groups. This is equivalent to running the <code>reset_path_group</code> command. Note: After deleting the existing path groups, new path groups, reg2reg and reg2cgate are created.

Examples

- The following command is used to create the standard path groups:

```
@[DEV]tempus 4> create_basic_path_groups
```

The software returns the following information:

```
Created reg2reg path group
```

```
Created reg2cgate path group
```

create_boundary_model

```
create_boundary_model  
[-help]  
-dir string  
[-exclude_no_delay_ports]  
[-include_full_parasitics]  
[-include_userpins <string>]  
[-latch_effort_low]  
[-overwrite]  
[-skip_constant_ports]  
[-skip_constants]  
[-skip_disabled]  
[-skip_ports string]
```

Initiates the creation of a boundary model from a full design.

Parameters

-help	Prints out the command usage.
-dir <i>string</i>	Specifies the directory for boundary model files.
-exclude_constraints	Does not include constraints in the generated model.
-exclude_no_delay_ports	Skips tracing logic through unconstrained input ports in the boundary model.
-include_full_parasitics	Allows you to write out RCDB parasitics for all lower-level blocks as part of the current boundary model. When specified, the software writes out full parasitics by running the write_rcdb command under the hood.
-include_userpins <i>string</i>	Includes the specified pins in the boundary model. No fanin/fanout tracing is performed for the specified pins.

<code>-latch_effort_low</code>	Skips tracing of logic through latch aggressors that are not part of the interface logic. The aggressors in the fanout of latch aggressors will use an infinite timing window. By default, the entire fanin cone of latch aggressors is preserved to ensure accurate latency adjustment, which may increase the size of the boundary model.
<code>-overwrite</code>	Allows overwrite of the existing directory.
<code>-skip_constant_ports</code>	Skips tracing logic through constant ports in the boundary model.
<code>-skip_constants</code>	Skips tracing through constant logic in the boundary model.
<code>-skip_disabled</code>	Skips tracing of logic through disabled arcs (user or constant disabled) in the boundary model.
<code>-skip_ports <i>string</i></code>	Skips tracing fanin/fanout logic through specified ports in the boundary model.

Examples

- The following command creates a boundary model for the top cell being timed and writes the model files into the `./model_dir` directory. Any existing directory contents are removed.

```
create_boundary_model -dir ./model_dir -overwrite
```

Related Commands and Variables

- `read_boundary_model`

create_constraint_mode

```
create_constraint_mode
[-help]
-name modeName
-sdc_files {file1.sdc file2.sdc ...}
[-ilm_sdc_files {file1.sdc file2.sdc ...}]
[-tcl_variables {{var_name1 value1} {var_name2 value2} {var_name3 value3} ...}]
```

Associates a list of SDC constraint files with a specified constraint mode name, for multi-mode multi-corner analysis. This constraint mode name can be referred to later when creating analysis views. A constraint mode defines one of possibly many different functional, test, or Dynamic Voltage and Frequency Scaling (DVFS) modes of a design. SDC files can be shared by many different constraint modes, and the same constraint mode can be associated with multiple analysis views.

SDC files typically contain timing analysis information, such as the clock specifications, case analysis constraints, I/O timings, and path exceptions that make each mode unique. If the ILM is being used, the timing system utilizes the files specified with `-ilm_sdc_files` during the flatten ILM mode (`flatten_ilm`); otherwise, the system uses the files specified with `-sdc_files`.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-ilm_sdc_files {<i>file1.sdc file2.sdc ...</i>}</code>	Specifies a Tcl list of ILM SDC files to be included in the constraint mode.
<code>-name <i>modeName</i></code>	Specifies the name of the constraint mode to be created.
<code>-sdc_files {<i>file1.sdc file2.sdc ...</i>}</code>	Specifies a Tcl list of SDC files to be included in the constraint mode.
<code>-tcl_variables {{<i>var_name1 value1</i>} {<i>var_name2 value2</i>} {<i>var_name3 value3</i>} ...}</code>	
	Specifies a list of tcl variables and values to be used in the constraint mode.

Examples

- The following command groups the SDC files `io.sdc`, `mission1-clks.sdc`, and `mission1-except.sdc` to create a mode object named `missionSetup`:

```
tempus> create_constraint_mode -name missionSetup  
-sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc]
```
- The following command groups the SDC files `io.sdc`, `mission1-clks.sdc`, `mission1-except.sdc`, and `dont_use.sdc` to create a mode object named `missionHold`:

```
tempus> create_constraint_mode -name missionHold  
-sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc dont_use.sdc]
```
- The following command groups the SDC files `test-io.sdc`, `test-clks.sdc`, and `test-except.sdc` to create a mode object named `testHold`:

```
tempus> create_constraint_mode -name testHold  
-sdc_files [list test-io.sdc test-clks.sdc test-except.sdc]
```

Related Commands

- `update_constraint_mode`
- `create_analysis_view`

create_delay_corner

```
create_delay_corner
[-help]
[-early_estimated_worst_irdrop_factor <percent>]
-name delayCornerName
[-early_irdrop_files list_of_files]
[-early_rc_corner rcCornerObj]
[-early_temperature_files list_of_files]
[-early_timing_condition conditional_pairs]
[-late_estimated_worst_irdrop_factor percent]
[-late_irdrop_data files_or_directories]
[-late_irdrop_files list_of_files]
[-late_rc_corner rcCornerObj]
[-late_temperature_files list_of_files]
[-late_timing_condition conditional_pairs]
[-irdrop_data files_or_directories]
[-irdrop_files list_of_files | -irdrop_data files_or_directories]
[-pg_net_voltages voltage_pairs]
[-rc_corner rcCornerObj]
[-si_enabled <true | false>]
[-temperature_files list_of_files]
[-timing_condition conditional_pairs]
```

Creates a named delay calculation corner object that can be referenced later when creating an analysis view. A delay calculation corner provides all of the information necessary to control delay calculation for a specific view. Each corner contains information on the libraries to use, the operating conditions with which the libraries should be accessed, and the RC extraction parameters to use for calculating parasitic data. Delay corner objects can be shared by multiple top-level analysis views.

 The `-early_*` and `-late_*` parameters should not be used to represent best and worst case corners. Instead use separate delay corners to define Best-Case and Worst-Case differences. Use the `-early_*` and `-late_*` parameters within a single delay calculation corner to control on-chip variation. In this latter situation different conditions or libraries will be used for the launch and capture paths of individual timing paths.

Note: A single delay calculation corner object specifies the delay calculation rules for the entire design. If a design includes power domains, the delay calculation corner can contain domain-specific subsections that specify the required operating condition information, and any necessary timing library rebinding for the power domain. Use the [update_delay_corner](#) command to add a power domain definition to a delay calculation corner.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-early_estimated_worst_irDrop_factor percent</code>	Specifies the early voltage derating factor. When this parameter is specified, the software performs delay calculations using the voltage = $\text{nomVolt} * (1 - \text{value})$. <i>Default: 0.0</i>
<code>-early_irdrop_data files_or_directories</code>	Specifies the IR drop files or directories to apply when calculating the early arrival times at a single delay corner.
<code>-early_irdrop_files list_of_files</code>	Specifies the list of IR drop files to apply when calculating early arrival times at a single power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. Note: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
<code>-early_rc_corner rcCornerObj</code>	Specifies the RC corner object to associate with the early corner object.
<code>-early_temperature_files list_of_files</code>	Specifies the name of the temperature file for temperature aware delay calculation for early corner.
<code>-early_timing_condition conditional_pairs</code>	Specifies pair list of domains/supply sets and timing conditions to associate with this delay corner object.
<code>-irdrop_data files_or_directories</code>	Specifies the IR drop files or directories to apply to both the early and late delay calculation for the specified delay corner object.

<code>-irdrop_files list_of_files</code>	Specifies the list of IR drop files to apply to both early and late delay calculation for this power domain object. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes. Note: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
<code>-late_estimated_worst_irDrop_factor percent</code>	Specifies the late voltage derating factor. When this parameter is specified, the software performs delay calculations using the voltage = $\text{nomVolt} * (1 - \text{value})$. <i>Default:</i> 0.0
<code>-late_irdrop_data files_or_directories</code>	Specifies the IR drop files or directories to apply when calculating the late arrival times at a single delay corner.
<code>-late_irdrop_files list_of_files</code>	Specifies the list of IR drop files to apply when calculating late arrival times at a single power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. Note: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
<code>-late_temperature_files list_of_files</code>	Specifies the name of the temperature file for temperature aware delay calculation for late corner.
<code>-late_rc_corner rcCornerObj</code>	Specifies the RC corner object to associate with the late corner object.
<code>-late_timing_condition conditional_pairs</code>	Specifies pair list of domains/supply sets and timing conditions to associate with this delay corner object. Note: The <code>-early_timing_condition</code> and <code>-late_timing_condition</code> parameters should be specified together.

<code>-name delayCornerName</code>	Specifies the delay calculation corner to which to add the power domain definition, or to which to update the delay corner or power domain attribute values.
<code>-pg_net_voltages voltage_pairs</code>	Specifies the power/ground net voltages to be used for both early/late timing analysis.
<code>-rc_corner rcCornerObj</code>	Specifies the new RC corner object to associate with this delay corner.
<code>-si_enabled {true false}</code>	Controls signal integrity (SI) analysis. When set to <code>true</code>, the analysis of all MMMC views will include SI analysis by default. You can use this parameter to further determine which analysis views receive SI analysis and which do not. When this parameter is set to <code>false</code> on a delay corner, the software will disable SI analysis for all the views that reference that corner. By default (or when this parameter is set to <code>true</code>), SI analysis is computed for all the views related to that corner - whenever SI is globally enabled. (The global control of SI analysis is determined by the <code>delaycal_enable_si true</code> attribute setting.)
<code>-temperature_files list_of_files</code>	Specifies the name of the temperature file for temperature aware delay calculation for single corner.
<code>-timing_condition conditional_pairs</code>	Specifies pair list of domains/supply sets and timing conditions to associate with this delay corner object.

Examples

- The following example specifies a list of conditional pairs of domains/supply sets and the timing conditions associated with the specified delay corner object:

```
create_delay_corner -name ccworst_setup\  
-timing_condition {tc_1 PD1@tc_2 PD2@tc_2 PD3@tc_2 PD4@tc_2}
```

Related Commands

- `update_delay_corner`

create_glitch_boundary_model

```
create_glitch_boundary_model  
[-help]  
[-add_bound_lib_report]  
[-bound_lib_report <string>]  
-dir string  
[-max_stages integer]  
[-overwrite]  
[-skip_constants]  
[-skip_constant_ports]  
[-skip_ports string]
```

Creates a boundary model for the current design for performing glitch analysis.

Parameters

<code>-help</code>	Prints out the command usage.
<code>- add_bound_lib_report</code>	Allows to write a report into the model directory as <code>bound_libs.rpt.gz</code> .
<code>-bound_lib_report <string></code>	Specifies the name of a file to which a report will be written if the bound library/libraries for every instance is included in the model. When this parameter is not specified, a report will not be written.
<code>-dir string</code>	Specifies the directory where the model will be saved. If a directory does not exist, it will be created. If it already exists, and the <code>-overwrite</code> parameter is specified, then the existing directory will be deleted first - otherwise an error will be displayed.
<code>-max_stages integer</code>	Specifies the maximum number of levels of interface logic to keep from the boundary ports. All the attackers to any net along the interface logic path will be kept along with the attacker's driver and receiver. When this parameter is specified, the glitch at the input to the interface paths to the output pins will be kept and fed into the internal nets of the block. <i>Default: 2</i>
<code>-overwrite</code>	Allows the software to replace any existing directory contents with the generated boundary model.
<code>- skip_constants</code>	Allows the software to skip any logic that is constant for all the views during the forward tracing from input ports to find timing endpoints. In addition, the fanin logic is not traced for output ports that are constant in all the views.
<code>-skip_constant_ports</code>	Ignores the timing endpoints driven exclusively by constant ports.
<code>-skip_ports string</code>	Specifies primary ports of a block that should be skipped when tracing the interface paths to be included in the model. The ports can be specified as a port name or list of port names. The forward tracing for finding endpoints will not be done from skipped input ports, and the fanin tracing will not be done from the skipped output ports. Note that timing endpoints that can be reached from both a skipped input port and a non-skipped input port will be included in the model. In such a case, the skipped input port will be included in the model since it is a part of the fanin logic of the endpoint. Note: This parameter does not support collections.

Examples

- The following command creates a boundary model in the specified directory and overwrites any existing directory contents:

```
create_glitch_boundary_model -dir model_dir -overwrite
```

- The following command creates a boundary model that keeps up to 6 stages of logic from the input ports and to the output ports of the design:

```
create_glitch_boundary_model -dir model_dir -max_stages 6
```

- The following command creates a boundary model that does not include any logic constrained as constant:

```
create_glitch_boundary_model -dir model_dir -skip_constants
```

- The following command creates a boundary model that does not include the fanout logic from input port “scan_in” or fanin logic to the output port “scan_out”:

```
create_glitch_boundary_model -dir model_dir -skip_ports {scan_in scan_out}
```

Related Commands

- `read_boundary_model`
- `create_boundary_model`

create_ipd_configuration

```
create_ipd_configuration
[-help]
[-no_commit | -load_constraints ]
[-no_commit | -load_derates ]
[-setup | -hold ]
[-setup | -bounded_corners ]
[-hold | -bounded_corners ]
[-min_bounded_corner | -setup | -bounded_corners | -max_bounded_corner ]
[-max_bounded_corner | -hold | -bounded_corners | -min_bounded_corner ]
[-min_bounded_corner | -pd_list <string>]
[-max_bounded_corner | -pd_list <string>]
[-hold | -pd_list <string>]
[-setup | -pd_list <string>]
[-bounded_corners | -pd_list <string>]
```

Creates IPD combinations or the analysis views in both the bounded scope generation and the scope analysis session.

This command automatically generates the views based on the `set_ipd_rail_voltage` settings and loads the view definition for IPD analysis.

Parameters

-help	Prints out the command usage.
-bounded_corners	Creates the minimum/maximum bounding voltage combinations to be used for analysis. This parameter is used only in scope creation run.
-load_constraints	Loads the constraints stored in IPD scope during scope analysis run. (Applicable only in IPD scope analysis.)
-load_derates	Loads the derates stored in the IPD scope during scope analysis run. (Applicable in only IPD scope analysis.)
-no_commit	Creates the IPD view definition file named, ipdViewDefinition.tcl - but does not load it. By default, the IPD view definition is read in automatically. This parameter is mutually exclusive to the <code>-load_derates</code> and <code>-load_constraints</code> parameters.

Examples

- The following example shows usage of `create_ipd_configuration` command in scope analysis run.

```
create_ipd_configuration -load_derates -load_constraints
```

The `-load_constraints` and `-load_derates` parameters are optionally used in the scope analysis session to load the constraints and derates stored in the IPD scope. This IPD rail voltage specification, creates 16 (2^4) views corresponding to 4 PG nets.

- The following command creates bounding IPD views:

```
tempus > set_ipd_rail_voltage -sweep { PGN1 {0.7 0.8} PGN2 {0.9 1.0} PGN3 {1.1 1.2} PGN4  
{0.6 0.7} }  
create_ipd_configuration -bounded_corners
```

This will create bounding IPD views with the following voltage combinations:

- minimum bounding view: PD1=0.8v PD2=1.0v PD3=1.2v PD4=0.7v
- maximum bounding view: PD1=0.7v PD2=0.9v PD3=1.1v PD4=0.6v

Related Commands

- `create_pg_net_group`

- `report_ipd_configuration`
- `write_ipd_scope`
- `read_ipd_scope`
- `report_ipd_crossings`

Related Information

- For more information, refer to the [Inter Power Domain \(IPD\) Analysis](#) chapter in the *Tempus Stylus User Guide*.

create_library_set

```
create_library_set
[-help]
[-library_side_file string]
-name libSetName
[-timing {lib1.lib lib2.lib lib3.lib ...}]
[-aocv string]
[-si {lib1.cdb lib2.cdb lib3.udn lib4.udn...}]
[-socv string]
```

Associates a TCL list of timing and cdB/UDN libraries with a specified library set name. Library sets allow a group of library files to be treated as a single entity so that higher-level descriptions (delay calculation corners) can simply refer to the library configuration by name. The same library set can be referenced multiple times by different delay calculation corners.

Note: You must have a set of timing libraries specified in the configuration file for the software to initialize properly. When configuring your multi-mode multi-corner environment, you can choose to specify these libraries in your own custom library set, or refer to them through the two library set definitions that are automatically initialized from the configuration file: `default_libs_min` and `default_libs_max`.

Note: The `create_library_set` command determines the priority of ECSM vs CCS data (if both are present). The software first checks for ECSM construct, if it is missing then CCS construct is loaded.

 The order in which you define timing libraries is important. The software considers the first library you specify in the list as the master library, with each successive library having a lower priority.

Parameters

-help	Prints out the command usage.
-aocv <i>string</i>	Specifies the aocv libraries to include in the library set.
-library_side_file <i>string</i>	Specifies the library side file.
-name <i>libSetName</i>	Specifies the name for the library set being created. This name is used to associate the library list with a specific delay calculation corner.

<pre>-si {lib1.cdb lib2.cdb lib3.udn lib4.udn...}</pre>	Specifies cdB libraries and/or user-defined noise (UDN) models to include in the library set. The cdB and/or UDN libraries are required for performing signal integrity analysis. Note: You can use this parameter for CCS-N or ECSM-N models, that is, for cdBs only.
<pre>-socv <i>string</i></pre>	Specifies the SOCV libraries to include in the library set.
<pre>-timing {lib1.lib lib2.lib lib3.lib...}</pre>	Specifies the timing libraries to include in the library set. Note: Libraries intended for use in an ECSM-based multi-library interpolation must be grouped within an additional level of Tcl list structure to identify the intended usage to the library subsystem. Specify three timing libraries that are characterized at different voltages (typically the lower and upper voltage bounds, and a third intermediate point). All voltages required by the software will be interpolated from this set of libraries. The libraries in the set can differ only in the characterization voltage; they must be identical to each other in all other aspects. However, if you want to perform multi-temperature based library interpolation, you can use two library files that are characterized at different temperatures for each voltage value. See the examples for creating an ECSM-based multi-library set and multi-temperature based library interpolation in the Examples section.

- i** The ECSM and CCS libraries can be very large and loading them may take significant time. You can convert the ASCII NLDM (Liberty .lib), ECSM, and CCS libraries to a binary version using the `write_ldb` command. For conversion of libraries to a binary version, refer to [write_ldb](#).

Instead of the original ASCII libraries, you can specify these binary libraries in the configuration file:

- **Original MMMC setup file:**

```
create_library_set -name libName -  
timing "AAA.lib BBB.ecsm CCC.ccs"
```

- **New MMMC setup file:**

```
create_library_set -name libName -  
timing "AAA.ldb BBB.ldb CCC.ldb"
```

Examples

- The following command creates a library set that associates timing libraries and cdB libraries with a nominal voltage of 1 volt with the library name IsCOM-1V:

```
tempus > create_library_set  
-name IsCOM-1V -timing [list stdcell_F_1V.lib ram_F.lib pad.lib]  
-si [list stdcell_F_2.cdb ram_F.cdb pad.cdb]
```

- The following command creates a library set that can be used to specify the 2-volt version of a core cell library, which could be associated later with a 2-volt MSMV power domain specified in the design:

```
tempus > create_library_set  
-name IsCOM-2V  
-timing [list stdcell_F_2V.lib]
```

- The following command creates an ECSM-based multi-library set called triLibFast. The libraries are grouped within an additional level of Tcl list structure to identify the intended usage to the library subsystem.

```
tempus > create_library_set  
-name triLibFast
```

```
-timing [list  
    [list stdcell_F_1V.lib stdcell_F_2V.lib stdcell_F_3V.lib]  
    ]  
    ram_F.lib pads.lib  
    ]
```

- The following command performs multi-temperature based library interpolation for libraries characterized at 0.7, 1.0, and 1.1 volts, each of which is also characterized using -40 and -35 temperature values:

```
tempus > create_library_set  
-name Trilib  
-timing {{ stdcell_0.7_temp-40.lib stdcell_0.7_temp-35.lib stdcell_1.0_temp-40.lib  
stdcell_1.0_temp-35.lib stdcell_1.1_temp-40.lib stdcell_1.1_temp-35.lib } mem.lib io.lib  
}
```

Related Commands

- `update_library_set`

create_opcond

```
create_opcond  
[-help]  
-name opcondName  
[-process processValue]  
[-temperature temperatureValue]  
[-voltage voltageValue]
```

Creates a set of virtual operating conditions in the specified library without actually modifying the library. These virtual operating conditions can then be referenced by a delay calculation corner ([create_delay_corner](#)) as if they actually exist in the library.

Parameters

-help	Prints out the command usage.
-name <i>opcondName</i>	Specifies the name for the operating condition being created.
-process <i>processValue</i>	Specifies the process value for the operating condition.
-temperature <i>temperatureValue</i>	Specifies the temperature value for the operating condition.
-voltage <i>voltageValue</i>	Specifies the voltage value for the operating condition.

Examples

- The following command creates a virtual operating condition called PVT1:

```
tempus> create_opcond -name PVT1  
-process 1.0  
-voltage 1.2  
-temperature 120
```

- The following command creates a virtual operating condition called PVT2:

```
tempus> create_opcond -name PVT2  
-process 1.0  
-voltage 1.2  
-temperature 20
```

Related Commands

- `create_delay_corner`
- `create_timing_condition`
- `update_timing_condition`

create_parasitic_coordinate_transform

```
create_parasitic_coordinate_transform
```

```
[-help]  
{-inst inst_name  
[-x_block_origin value  
[-x_offset value  
[-y_block_origin value  
[-y_offset value  
[-orient {R0 R90 R180 R270 MY MX90 MX MY90}]]  
[-relative_to_parent]] | {-reset}}
```

Determines accurate location information of nodes during SPEF reading.

In case of hierarchical designs, there can be multiple blocks in a design that are implemented separately. During Top level STA analysis, SPEFs of these blocks are stitched together with top for flat STA analysis. This works well if pin location of blocks is not required. In case of AOCV analysis, when spatial analysis is enabled, accurate location of all nodes (pin/net) in the design is required for calculating accurate derates in the design. This makes it necessary to determine accurate nodes location during SPEF reading. This can be achieved by transforming SPEF coordinates as per their physical locations.

Note:

- This command works with all possible SPEF and RCDB input combinations with `read_parasitics` command, which means for only RCDB(s) as input, mix of SPEF(s) and RCDB(s) as input and only SPEF(s) as input.
- If this command is not specified, the `read_spef` command tries to automatically find the orientation and origin of the hierarchical SPEF blocks and applies those identified transforms to the parasitic co-ordinates.
- The `create_parasitic_coordinate_transform` command settings remain in effect for all the subsequent `read_spef` and `read_parasitics` until they are reset using the `-reset` option.
- Whenever the block's origin (in block SPEF/DEF) is non-zero, the x and y coordinates need to be specified for applying the transform. The last two parameters, `-x_block_origin` and `-y_block_origin` in the following command use-model are only required to be specified for the case of non-zero block origin.

```
create_parasitic_coordinate_transform -inst inst_name  
-x_offset x-offset of block origin in top-level DEF/SPEF  
-y_offset y-offset of block origin in top-level DEF/SPEF  
-orient orientation  
-x_block_origin x-coord of non-zero block origin
```

`-y_block_origin` *y-coord of non-zero block origin*

For example:

- **For Non-Zero Origin Block:** Specify the block origin as shown below:

```
create_parasitic_coordinate_transform -inst eco_inst1
-x_offset 421.6
-y_offset 485
-orient R180
-x_block_origin 3.4
-y_block_origin 9.7
```

- **For zero origin block:** No need to specify the block origin as shown below:

```
create_parasitic_coordinate_transform
-inst controller
-x_offset 16.8
-y_offset 205
-orient R0
or
create_parasitic_coordinate_transform
-inst controller
-x_offset 16.8
-y_offset 205
-orient R0
-x_block_origin 0
-y_block_origin 0
```

Both the above commands are equivalent.

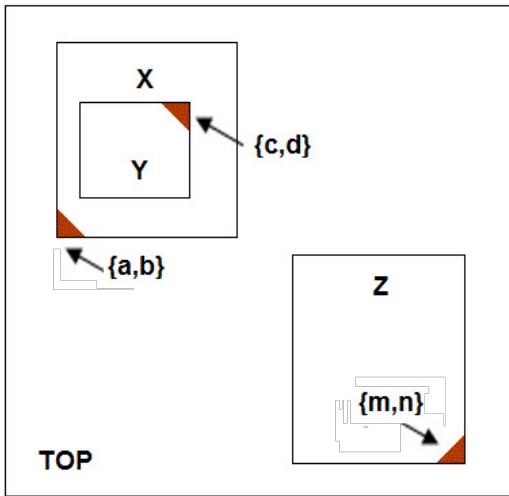

- The impact of this command is valid till first `read_spef` command is read (in case of MMMC, till all corners SPEFs have been read). If you want to read SPEF again, this command needs to be applied once again. These transformations will be applied during `read_spef` command.

Parameters

<code>-help</code>	Prints out the command usage. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man create_parasitic_coordinate_transform</code>
<code>-inst inst_name</code>	Indicates the hierarchical name of the instance for which SPEF is being read.
<code>-orient {r0 r90 r180 r270 my mx90 mx my90}</code>	Indicates orientation change of instances. The valid values are <code>R0</code> , <code>R90</code> , <code>R180</code> , <code>R270</code> , <code>MX</code> , <code>MX90</code> , <code>MY</code> , and <code>MY90</code> .
<code>-relative_to_parent</code>	When this parameter is specified, the software considers block offsets for the specified instance relative to the immediate parent. By default, the software considers the offset value relative to the top hinst.
<code>-reset</code>	Resets SPEF transform values.
<code>-x_block_origin value</code>	Specifies that in case of non-origin block, offset x-coordinate in microns
<code>-x_offset value</code>	Indicates the actual x-coordinate as exists in the physical floor plan, corresponding to the specified instance.
<code>-y_block_origin value</code>	Specifies that in case of non-origin block, offset y-coordinate in microns
<code>-y_offset value</code>	Indicates the actual y-coordinate as exists in the physical floor plan, corresponding to specified instance.

Examples

Consider the following hierarchical design where X and Z are two blocks inside TOP, and Y is another hierarchical block in X:

Here, X,Y, and Z have the following physical locations in the floor plan:

X - (a,b)
Y- (c,d)
Z- (m,n)

You can apply transformations to all blocks with respect to TOP, by using the following commands:

```
tempus> create_parasitic_coordinate_transform -inst X -x_offset a -y_offset b
tempus> create_parasitic_coordinate_transform -inst Z -x_offset m -y_offset n -orient MY
tempus> create_parasitic_coordinate_transform -inst X/Y -x_offset c -y_offset d -orient R180
```

These transformations will be applied when `read_spef` command is issued.

Related Commands

- `set_analysis_view`
- `redirect`
- `read_parasitics`
- `read_spef`
- `report_parasitic_coordinate_transforms`

create_pg_net_group

```
create_pg_net_group  
[-help]  
-name <name>  
-pg_nets <net>
```

Allows you to group a set of PG nets. This helps in simplification of overall UI of the IPD flow by specifying sweeps for a PG net group rather than a PG net. Also, the IPD crossings between the PG nets within a PG net group are automatically ignored.

Parameters

-help	Prints out the command usage.
-name <name>	Specifies the PG net group name.
-pg_nets <net>	Specifies a list of power nets.

Examples

- In the following example, the PG nets pgn1, pgn2, and pgn3 are a part of the PG net group PG1.

```
create_pg_net_group -name PG1 -pg_nets {pgn1 pgn2 pgn3}  
set_ipd_rail_voltage -sweep { PG1 {0.7 0.8} }
```

The voltage values specified for PG1 are applicable for the PG nets that are part of the PG net group. The crossings between pgn1 and pgn2, pgn2 and pgn3, and pgn1 and pgn3 will be ignored automatically.

- In the following example, the PG nets pgn1, pgn2, and pgn3 are part of PG net group PG1:

```
tempus > create_pg_net_group -name PG1 -pg_nets {pgn1 pgn2 pgn3}  
tempus > create_delay_corners -name dc1 -library_set libset1 -rc_corner rc1 -  
pg_net_voltages {PG1@0.7}
```

The voltage values specified for PG1 are applicable for the PG nets that are part of this PG net group (defined using `create_delay_corner -pg_net_voltages`).

Related Commands

- `report_pg_net_group`
- `create_ipd_configuration`
- `report_ipd_configuration`
- `write_ipd_scope`
- `read_ipd_scope`
- `set_ipd_rail_voltage`

Related Information

- For more information, refer to the [Inter Power Domain \(IPD\) Analysis](#) chapter in the *Tempus Stylus User Guide*.

create_property_alias

```
create_property_alias
[-help]
-map <alias_property_name_pairs>
-obj_type {pin port cell net clock lib_cell lib_pin design lib timing_path timing_point
timing_arc path_group lib_timing_arc si_victim si_attacker lib_pg_pin pg_pin pg_net}
```

Creates a property alias for the selected objects.

Parameters

-help	Prints out the command usage.
-map <alias_property_name_pairs>	Specifies a pair list of aliases and properties to be associated with that alias, such as {alias1 prop1} or {{ialias1 prop1}{alias2 prop2}...}.
-obj_type {pin port cell net clock lib_cell lib_pin design lib timing_path timing_point timing_arc path_group lib_timing_arc si_victim si_attacker lib_pg_pin pg_pin pg_net}	Specifies the object type for which a property alias needs to be created.

create_rc_corner

```
create_rc_corner  
[-help]  
[-cap_table capTableFile]  
-name rcCornerName  
[-post_route_cap {capFactor1 capFactor2 capFactor3}]  
[-post_route_clock_cap {capFactor1 capFactor2 capFactor3}]  
[-post_route_clock_res {resFactor1 resFactor2 resFactor3}]  
[-post_route_res {resFactor1 resFactor2 resFactor3}]  
[-post_route_cross_cap {xcapFactor1 xcapFactor2 xcapFactor3}]  
[-pre_route_cap capFactor]  
[-pre_route_clock_cap capFactor]  
[-pre_route_clock_res resFactor]  
[-pre_route_res resFactor]  
[-qrc_tech fileName]  
[-temperature temperatureValue]  
[-via_variation_file string]
```

Creates a named RC corner object that can be referenced later when creating a delay calculation corner object. An RC corner object provides the software with all of the information necessary to properly extract, annotate, and use the RCs for delay calculation.

Note: You must use the RC corner scaling attributes when running the software in multi-mode multi-corner analysis mode. Use the [extract_rc Category Attributes](#) to set the extraction mode for all RC corner objects in the design.

Note: In multi-mode multi-corner mode, only the default RC corners created by the software inherit the derating factor values defined in the configuration file. You can set different postroute scale factors for the postroute engine variants by specifying them as duplets and triplets. For example,

```
resFactor1 resFactor2 resFactor3
```

Where:

- Single value: If you specify one value, the scale factor applies to effort level `low`. Scale factor value of 1 is used for `medium` and `high` by default.
- Duplet: If you specify two values, the first value is used for effort level `low` and the second value is used for `medium`. Scale factor value of 1 is used for `high` by default.
- Triplet: If you specify three values, the first value is used for effort level `low`, the second value is used for `medium`, and the third value is used for `high`.

Note: If the [read_spef](#) command is specified without the `-rc_scale` parameter, for example, "`read_spef -rc_corner early_spef_${rc_corner}`", then the software does not apply capacitance scale factor specified in `-post_route_cap` and `-post_route_cross_cap` parameters. If the `read_spef` command is

specified with the `-rc_scale` parameter, for example, `"read_spef -rc_corner early_spef_${rc_corner} -rc_scale "`, then the software applies the capacitance scale factor. Here, no factor is specified in the `-rc_scale` option.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>create_rc_corner</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man create_rc_corner</code> .
<code>-cap_table capTableFile</code>	Specifies the capacitance table to use for extraction when using this RC corner. <i>Default:</i> The Tempus extraction system uses internal rules for extracting resistances and capacitances.
<code>-pre_route_cap capFactor</code>	Specifies the capacitance scale factor for RC Extraction in pre-route mode. <i>Default:</i> 1.0
<code>-pre_route_clock_cap capFactor</code>	Specifies the scale factor for capacitance of clock nets in preroute mode. <i>Default:</i> 0 When this parameter is not specified, the value specified with the <code>-pre_route_cap</code> parameter is used for preroute extraction. When specified, this parameter overrides the value specified with the <code>-pre_route_cap</code> parameter for clock nets.

<pre>-pre_route_clock_res resFactor</pre>	Specifies the scale factor for resistance of clock nets in preroute mode. <i>Default:</i> 0 When this parameter is not specified, the value specified with the <code>-pre_route_res</code> parameter is used for preroute extraction. When specified, this parameter overrides the value specified with the <code>-pre_route_cap</code> parameter for clock nets.
<pre>-pre_route_res resFactor</pre>	Specifies the resistance scale factor for RC extraction in pre-route mode.
<pre>-post_route_cap {capFactor1 capFactor2 capFactor3}</pre>	Specifies the capacitance scale factor for RC extraction in post-route mode. <i>Default:</i> 1.0
<pre>-post_route_clock_cap {capFactor1 capFactor2 capFactor3}</pre>	Specifies the scale factor for capacitance of clock nets in the postroute extraction mode. <i>Default:</i> 0 When this parameter is not specified, the value specified with the <code>-post_route_cap</code> parameter is used for postroute extraction. When specified, this parameter overrides the value specified with the <code>-post_route_cap</code> parameter.
<pre>-post_route_clock_res {resFactor1 resFactor2 resFactor3}</pre>	Specifies the scale factor for resistance of clock nets in the postroute extraction mode. <i>Default:</i> 0 When this parameter is not specified, the value specified with the <code>-post_route_res</code> parameter is used for postroute extraction. When specified, this parameter overrides the value specified with the <code>-post_route_res</code> parameter for clock nets.
<pre>-post_route_res {resFactor1 resFactor2 resFactor3}</pre>	Specifies the resistance scale factor for RC extraction in post-route mode.

<pre>-post_route_cross_cap {xcapFactor1 xcapFactor2 xcapFactor3}</pre>	Specifies the coupling capacitance scale factor for RC extraction in postroute mode. <i>Default:</i> 1.0
<pre>-name rcCornerName</pre>	Specifies the name for the RC corner object being created. You can choose any name for an RC corner object, but it is recommended that you use a name that can be easily recognized as referring to a specific RC corner (for example, rc-min, rc-max, c-min, c-max, and so on).
<pre>-qrc_tech fileName</pre>	Specifies the name of the Quantus technology (.tch) file used by Quantus sign-off RC extraction. The technology file is generated by TechGen, a built-in functionality of Quantus. For most technologies you can get this file from technology vendors. For technologies that are not available through the technology vendors, you can enter the fabrication process information into an ASCII-format interconnect technology (ICT) input file. The ICT file is then used as input to IceCaps, which in turn generates the technology file.
<pre>-temperature temperatureValue</pre>	Specifies the temperature, in units of Celsius, to use to derate resistance values. Use this parameter when you want to override the default temperature specified in the capacitance table or the Quantus technology file. Note: The software does not require that the temperature specified by the PVT operating condition at the delay calculation corner level be the same as the RC nominal or user-specified temperature value. <i>Default:</i> The Tempus extraction system uses the default temperature of 25 degrees Celsius, unless it is overridden by the capacitance table or the Quantus technology file.

`-via_variation_file string`

Specifies a file for modeling via variation. The VIA variation file lists up all the VIA layer names with the corresponding multiplier. Each RC corner can have its own VIA variation file.

For example:

```
create_rc_corner
-name rcCornerName1 \
-via_variation_file viaVariationFileName1
create_rc_corner
-name rcCornerName2 \
-via_variation_file viaVariationFileName2
```

Examples

- The following command creates an RC corner called `rc-cbest` that uses the capacitance table `myTech_4_bc.CapTbl`, and derates the resistance values based on the temperature of 50 Celsius:
`create_rc_corner -name rc-cbest -cap_table myTech_4_bc.CapTbl -temperature 50`

Related Commands

- `update_rc_corner`

create_timing_condition

```
create_timing_condition  
[-help]  
-library_sets string  
-name timingConditionName  
[-opcond string]  
[-opcond_library string]
```

Creates a set of virtual operating conditions in the specified library.

Parameters

-help	Prints out the command usage. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man create_timing_condition</code> .
-library_sets <i>string</i>	Specifies a list of library sets to associate with the specified timing condition.
-name <i>timingConditionName</i>	Specifies a unique name for the timing condition.
-opcond <i>string</i>	Specifies a single name of an operating condition to associate with this timing condition.
-opcond_library <i>string</i>	Specifies the name of library to search for the named operating condition. Notes: • The opcond library must be a library name, and not a library file path. • In a trilib flow, where multiple library sets of different PVTs are used for opcond interpolation, the opcond library should be close to the operating condition.

Examples

- The following commands create a set of timing conditions for the defined list of library sets:

```
create_library_set -name ls -timing [list typical.lib]
create_timing_condition -name tc1 -library_sets [list ls]
```

- The following commands create a set of virtual operating and timing conditions on the defined library sets:

```
create_opcond -name OC -process 1 -voltage 0.8 -temperature 25
create_timing_condition -name tc1 -library_sets [list ls] -opcond OC
```

Related Commands

- `update_timing_condition`

delete_analysis_view

```
delete_analysis_view  
[-help]  
analysis_view_list
```

Deletes the specified analysis views.

Parameters

-help	Prints out the command usage.
analysis_view_list	Specifies the list of views for deleting.

Related Commands

- `create_analysis_view`
- `update_analysis_view`
- `set_analysis_view`
- `report_analysis_views`

get_capacitance_unit

get_capacitance_unit

Returns the capacitance unit (in picofarads) for the current session, which may be derived from the library file or set with the `set_library_unit -cap` parameter. This unit will be used while generating reports and for constraint settings.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

Example

The following command returns the session capacitance unit:

```
get_capacitance_unit
```

```
1.000000pf
```

Related Commands

- `set_library_unit`

get_clock_network_objects

```
get_clock_network_objects  
[-help]  
[-clocks clock_list]  
[-type {cell | pin}]
```

Returns the cells or pins that exist in a clock network of the specified clocks.

Parameters

-help	Prints out the command usage.
-clocks <i>clock_list</i>	Returns the cells or pins present in a clock network of the specified clock(s).
-type {cell pin}	Returns the specified cells or pins in the clock network.

Examples

- The following command returns the pins present in the clock network of all the clocks:
tempus > get_clock_network_objects
- The following command returns the pins that exist in the clock network of CLK and CLK2 clocks:
tempus > get_clock_network_objects -clocks {CLK CLK2}
- The following command returns the cells that exist in the clock network of CLK clock.
tempus > get_clock_network_objects -clocks {CLK} -type cell

get_clock_to_clock_association

```
get_clock_to_clock_association  
[-help]  
clock_list  
[-allow_paths]  
[-group_name group_name]  
[-type {logically_exclusive | physically_exclusive | asynchronous}]  
[-view viewName]
```

Reports clock to clock associations.

Parameters

-help	Prints out the command usage.
clock_list	Specifies a list of clocks that must contain two entries.
-allow_paths	Checks whether the two specified clocks are asynchronous and timing analysis is allowed between these clocks.
-group_name group_name	Reports clock to clock association for the specified clocks along with the clock group name.
-type {logically_exclusive physically_exclusive asynchronous}	Checks clock to clock association for the specified type of clocks. You can use one of the following options: - logically_exclusive: Reports clock group with clocks that do not have any functional paths between them, but coexist in the design at the same time. - physically_exclusive: Reports clock group with clocks that cannot exist in the design at the same time. - asynchronous: Reports clock group with asynchronous clocks. Asynchronous clocks have no specified phase relationship.
-view viewName	Generates a report for the specified analysis view.

Related Commands

- `create_clock`
- `create_generated_clock`
- `set_clock_groups`

get_constant

```
get_constant  
[-help]  
[-input_side | -output_side]  
pin_port_obj
```

Queries the design database for the state of the specified pin or the state propagated through the combinational logic cone to that pin. The returned value is 0 for logic 0, 1 for logic 1, x for undefined, and z for tristate.

Note: Constants on hierarchical ports are not computed.

-  The `get_constant` command returns the state for one pin only. If you want to know the state on all ports that have a constant set, use the `-type constant` option with the `report_ports` command. For example:
`report_ports -type constant`. Use the `-tcl_list` option to process the list in Tcl.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-input_side -output_side</code>	Returns the constant that is set on the input or output part of bidirectional pins. <i>Default:</i> Returns the constant on the output part.
<code>pin_port_obj</code>	Specifies the name of the single pin to query for pin state. The pin must be an instance pin or primary I/O port.

Examples

- The following command sets the value of the specified pin(s) to either a 1 or 0 for use by the timing engine:
`set_case_analysis 0 J_block/zbuf0/A`
- The following command queries the design database for the state of the specified pin or the state

propagated through the combinational logic cone to that pin:

```
get_constant J_block/zbuf0/A
```

Related Commands

- `report_ports`
- `set_case_analysis`
- `report_case_analysis`

get_interactive_constraint_modes

`get_interactive_constraint_modes`

Returns a list of the multi-mode multi-corner constraint modes that are in interactive constraint entry mode.

When the software is in interactive constraint entry mode (`set_interactive_constraint_modes`), any timing constraints you specify take effect immediately on all active analysis views that are associated with these constraint modes.

Note: Interactive constraint mode only works when the software is in multi-mode multi-corner timing analysis mode.

Related Commands

- `set_interactive_constraint_modes`

get_propagated_clock

```
get_propagated_clock  
[-help]  
[-clock clock_list] [-pin pin_list]  
[> filename]
```

Returns the clock propagation mode, either `ideal` or `propagated`, for the specified clocks or pins.

Parameters

<code>-help</code>	Prints out the command usage.
<code>> <i>filename</i></code>	Specifies the name of a file in which to save the report. You can add the <code>.gz</code> extension to the file name to generate a compressed report. Note: The file name must be the last argument in the list.
<code>-clock <i>clock_list</i></code>	Specifies one or more clock waveforms for which you want to retrieve the clock propagation mode information.
<code>-pin <i>pin_list</i></code>	Specifies one or more pins or ports for which you want to retrieve the clock propagation mode information. You cannot specify hierarchical pins.

Examples

- The following command gets the clock propagation mode information for all clock waveforms:
`get_propagated_clock -clock {*}`

Related Commands

- `set_propagated_clock`

get_resistance_unit

`get_resistance_unit`

Returns the resistance unit for the current session.

Example

The following command returns the resistance unit for the current session:

```
get_resistance_unit
```

```
1.000000 kohm
```

get_socv_rc_variation_factor

```
get_socv_rc_variation_factor  
[-help]  
-view viewName  
{-early | -late}
```

Displays the variation factor for interconnect delays.

Parameters

-help	Prints out the command usage.
-early	Displays the variation factor for early interconnect delays.
-late	Displays the variation factor for late interconnect delays.
-view <i>viewName</i>	Displays the SOCV interconnect variation factor for specified view.

Related Commands

- `set_socv_rc_variation_factor`

get_socv_reporting_nsigma_multiplier

```
get_socv_reporting_nsigma_multiplier  
[-help]  
-view viewName  
{[-setup | -hold ]}
```

Allows you to query sigma multiplier setting for the specified view in setup or hold mode.

Parameters

-help	Prints out the command usage.
-hold	Returns the sigma multiplier for hold mode.
-setup	Returns the sigma multiplier for setup mode.
-view <i>viewName</i>	Returns the sigma multiplier value for the specified view. Note: Applies to active views only.

Examples

- The following command displays the sigma multiplier setting for the specified view:

```
tempus > set_socv_reporting_nsigma_multiplier -hold 2.5 -view default_emulate_view_hold  
tempus > get_socv_reporting_nsigma_multiplier -view default_emulate_view_hold -hold  
2.500000
```

Related Commands

- `set_socv_reporting_nsigma_multiplier`

get_time_unit

```
get_time_unit  
[-help]
```

Returns the current time unit (in nanoseconds) for the session derived from the library file or set with the `set_library_unit -time` parameter. This unit will be used during report generation and constraint settings.

Parameters

<code>-help</code>	Prints out the command usage.
--------------------	-------------------------------

Example

- The following command returns the time unit for the session:

```
get_time_unit
```

```
1.000000ns
```

Related Commands

- `set_library_unit`

gui_show_timing_map

```
gui_show_timing_map
[-help]
[-step float]
[-threshold float]
{-check_type {setup | hold} | -clear}
```

Displays the timing map in the Tempus GUI.

Parameters

-help	Prints out the command usage.
-check_type {setup hold}	Specifies the check type - setup or hold.
-clear	Clears the timing map.
-step float	Specifies the step.
-threshold float	Specifies the slack threshold.

list_libraries

```
list_libraries  
[-help]  
[-power_domain string]  
[-used]  
[-used_analysis]  
[-view string]
```

Lists all the libraries loaded in the session and used in the design.

Parameters

-help	Prints out the command usage.
-power_domain <i>string</i>	Specifies the power domain from which instances are to be selected.
-used	Prints out a list of libraries used in the design and all the other libraries, whose voltages match with those of the used libraries (like vt variant libraries). This list is useful for ECO optimization.
-used_analysis	Prints out a list of used libraries in the design.
-view <i>string</i>	Specifies the view name whose libraries will be listed.

Examples

Here are some examples.

- The following command reports all the libraries loaded in a session:

```
tempus> list_libraries
```

```
Library    Library    Library  
Group      Name       Path  
-----

merge_timing_reports

```
merge_timing_reports  
[-help]  
[-base_dir string]  
-base_report string  
[-command {report_constraint | report_timing | report_clock_timing}]  
[-max_paths integer]  
[-nworst integer]  
[-text]  
-view_dirs view_list  
> file_name
```

Merges machine-readable/text timing reports from the specified analysis views into a single report file. The software merges the reports based on the slack value. The path with the most critical slack is listed first in the report.

The `merge_timing_reports` command can be used for both single CPU and distributed multi-mode multi-corner timing analysis.

Note: This command should only be used in DMMMC master script after reports are generated from the `distribute_views` command.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-base_dir string</code>	Specifies the path to the output directory where the view-specific directories exist. The software looks in this directory for the base file name in the view specific directories, and then places the merged output in the specified redirection file. If it is not specified then software uses the base directory as the one specified with "distribute_read_design -outdir" option.
<code>-base_report string</code>	Specifies the base file name of the timing reports to merge.
<code>- command {report_constraint report_timing report_clock_timing}</code>	Merges the text timing reports from the specified file names. The generated timing reports can be from the commands <code>report_constraint</code> , <code>report_timing</code> , or <code>report_clock_timing</code> .
<code>file_name</code>	Specifies the name of the file in which to merge the timing reports.
<code>-max_paths integer</code>	Reports the top N worst paths that are picked from multiple views.
<code>-nworst integer</code>	Specifies to have at the most n paths per end point in a merged report.
<code>-text</code>	Generates merged report in the text format. Note: You can use this option only when the input reports are machine-readable.
<code>-view_dirs view_list</code>	Merges timing reports from the specified directories.

Examples

Here are some examples.

- The following command merges the machine-readable timing reports with the base file name `rt_setup1.rpt` in the analysis views `v1`, `v2`, and `v3` into a single machine readable timing report called `merged_report.rpt`:

```
tempus > merge_timing_reports -view_dirs {v1 v2 v3} -base_report rt_setup1.rpt >  
merged_report.rpt
```
- The following command merges the machine-readable timing reports with the base file name `rt_setup1.rpt` in the analysis views `v1`, `v2`, and `v3` into a single text timing report called `merged_report.rpt`:

```
tempus > merge_timing_reports -view_dirs {v1 v2 v3} -base_report rt_setup1.rpt -text > merged_report.rpt
```

- The following commands merge text timing reports (from `report_timing` command) with the base file name `topPaths.rpt` in the analysis views `v1` and `v2` into a single timing report called `merged_topPaths.rpt`:

```
tempus > distribute_command {report_timing -max_paths 10 > topPaths.rpt}
tempus > merge_timing_reports -command report_timing -view_dirs {v1 v2} -base_report topPaths.rpt -base_dir dmmmc_run_dir > merged_topPaths.rpt
```

- The following commands merge text timing reports (from `report_constraint` command) with the base file name `allViol.rpt` in the analysis views `v1` and `v2` into a single timing report called `merged_allViol.rpt`:

```
tempus > distribute_command {report_constraint -all_violators > allViol.rpt}
tempus > merge_timing_reports -command report_constraint -view_dirs {v1 v2} -base_report allViol.rpt -base_dir dmmmc_run_dir > merged_allViol.rpt
```

read_boundary_model

```
read_boundary_model
[-help]
[-check_contents]
[-instances string]
[-report_file string]
[-skip_version_check]
[-unconstrained_net_use_infinite_timing_windows]
[-clock_mapping_file string]
[-view_mapping_file string]
{-dir string}
```

Saves the directory information.

This command can be used for each cell boundary model generated by the block-level runs.

Parameters

-help	Prints out the command usage.
-check_contents	Checks for required files in the boundary model directory.

<code>-clock_mapping_file string</code>	Specifies the block to top-level clock mapping file. This command uses the mapping file created by the <code>set_boundary_model_clock_mapping</code> command. The basic syntax of <code>-clock_mapping_file</code> is: <pre>Block_clock_name (view_name) Top_clock_name (view_name) instance_name</pre> However, both <code>view_name</code> and <code>instance_name</code> are optional. If you want to have the same mapping for all instances and views then it is specified as follows: <pre>Block_clock_name Top_clock_name</pre> • If it is instance specific but not view specific then it is specified as follows: <pre>Block_clock_name Top_clock_name instance_name</pre> • If it is view specific but not instance specific then it is specified as follows: <pre>Block_clock_name (view_name) Top_clock_name (view_name)</pre> Note that no spaces are currently allowed between the clock name and the view name.
<code>-dir string</code>	Specifies the directory for boundary model.
<code>-instances string</code>	Specifies the instances for which the boundary model must be read.
<code>-report_file string</code>	Specifies the name of the boundary model check report file. After the boundary model is checked and the results are logged into this file. If this parameter is not specified, then by default the report gets written to <code><cell_name>_bmodel_check.txt</code> file.
<code>-skip_version_check</code>	Does not check for Tempus version consistency.
<code>-unconstrained_net_use_infinite_timing_windows</code>	Forces unconstrained nets to infinite timing windows.

`-view_mapping_file string`

Uses the mapping file created by the
`set_boundary_model_view_mapping` command.

Examples

- The following command loads the boundary model files from the `./model_dir` directory:

```
read_boundary_model -dir ./model_dir
```

- The following command loads the boundary model files from the `./model_dir` directory:

```
read_boundary_model -dir ./model_dir -clock_mapping_file clock.data
```

The `clock.data` file will be read for user-defined updates for clock mappings from the boundary model clock names to the clocks defined in the constraints for the current session.

Related Commands and Variables

- `create_boundary_model`
- `set_boundary_model_view_mapping`
- `set_boundary_model_clock_mapping`

read_ipd_scope

```
read_ipd_scope  
[-help]  
[<dir_name>]
```

Loads the scope data in the scope analysis run.

Parameters

-help	Prints out the command usage.
<dir_name>	Specifies the scope directory containing the minimum/maximum IPD scopes.

Examples

- The following command shows the usage of `read_ipd_scope` in scope analysis session.

```
tempus > read_ipd_scope bounded_corner_scope
```

Related Commands

- `report_pg_net_group`
- `create_ipd_configuration`
- `report_ipd_configuration`
- `write_ipd_scope`
- `set_ipd_rail_voltage`
- `report_ipd_crossings`

Related Information

- For more information, refer to the [Inter Power Domain \(IPD\) Analysis](#) chapter in the *Tempus Stylus User Guide*.

read_path_descriptions

```
read_path_descriptions
[-help]
filename
[-hpin]
[-path_type {end summary full full_clock end_slack_only summary_slack_only}]
[-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation waveform_propagation}]
```

Reads the file created by the `write_path_descriptions` command.

This command reads the complete description of the paths specified in the file from another Tempus session and returns the data as a timing path collection. The paths description when read back can be used as a regular path collection for any reporting command or queried using the `get_property` command.

Parameters

<code>-help</code>	Prints out the command usage.
<code>filename</code>	Specifies the name of the input file.
<code>-hpin</code>	Prints all the hierarchical crossings of an arc under the "hpin" column in the <code>report_timing</code> table.
<code>-path_type {end summary full full_clock end_slack_only summary_slack_only}</code>	Allows you to choose the format of the report based on the path type.
<code>-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation waveform_propagation}</code>	Reanalyzes the specified set of paths using the specified analysis method.

Examples

- The following example command reads out the pathfile1.txt. The file contains details of the collection of timing paths with hierarchical pins (`-hpin`) format based on timing and exact path availability in the session in which the path description is read:

```
read_path_descriptions pathfile1.txt -hpin
```

- The following command reads in a path descriptions file and queries the slack:

```
tempus > set read_paths_coll [read_path_descriptions path_desc.txt]
```

```
tempus > get_property $read_paths_coll slack  
-0.123
```

The following command generates a timing report from the path descriptions file:

```
tempus > report_timing [read_path_descriptions path_desc.txt] > paths.rpt
```

Related Commands

read_sdf

```
read_sdf
[-help]
sdf_file_name
[-continue_on_error]
[-ilm_filter]
[-incremental]
[-overwrite_incremental_delay]
[-path instanceName]
[-persistent]
[-report_summary]
[-scale float]
[-strict_cond_matching]
[-view viewName]
[-sdf_field {min|typ|max} | [-early_sdf_field {min|typ|max}] [-late_sdf_field {min|typ|max}]]
```

Reads an OVI Standard Delay Format (SDF) file and annotates user-specified delay information from the SDF file into the timing system. You can use the `read_sdf` command to supply precalculated delays and timing check values from an external delay calculator, or from a previous Tempus System session.

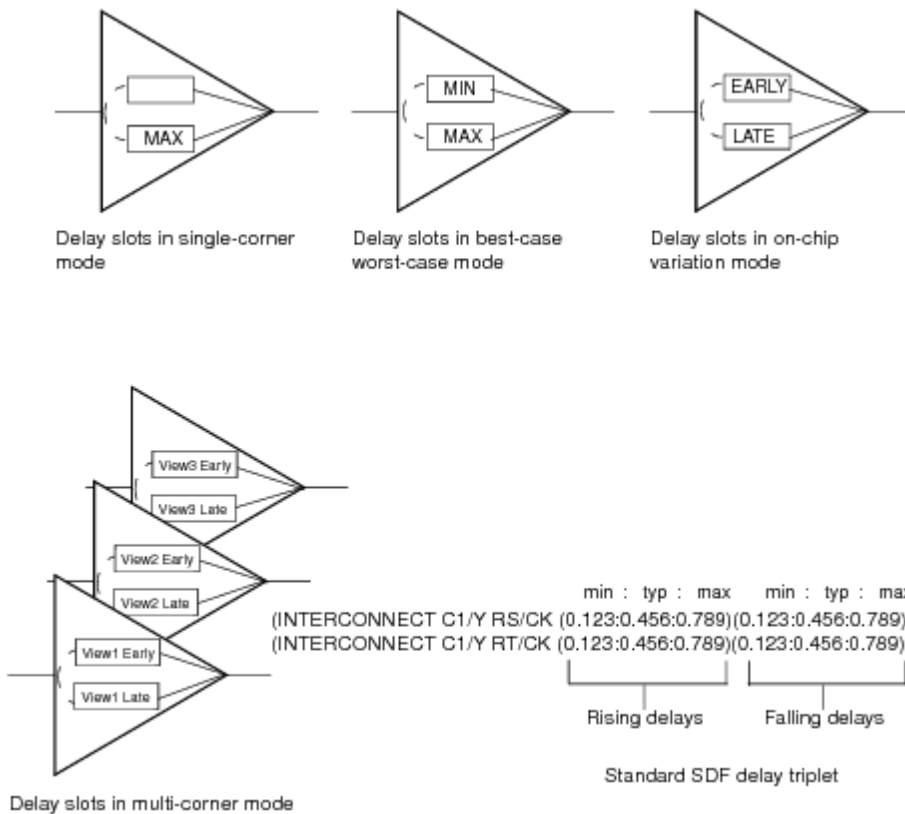

The `read_sdf` command can read version 2.1 and 3.0 of the SDF files, and can read both plain-text and GNU zipped (`.gz`) format files. The command and the Tempus System software do not support the Timing Environment section of the SDF specification.

The SDF file can provide one, two, or three different values for each timing arc delay or timing check value. These values are passed in the min, typ, or max SDF delay fields, represented as min:typ:max.

The Tempus System software provides multiple delay place holders to store the calculated or annotated delay information:

- In single-corner analysis mode, only max delays are available.
- In best-case worst-case mode, a min delay slot is provided for storing min delays used for hold analysis. A max delay slot stores delays used for setup analysis.
- In on-chip variation mode, the early delay slots store delays used for calculated early arrival times. The late delay slot stores delays used for calculated late arrival times.
- In multi-corner mode, an early and a late delay slot are provided for each multi-mode multi-corner analysis view.

The `read_sdf` command provides parameters for controlling how the SDF min:typ:max triplet values are mapped into the Tempus System software's delay slots. The correct mapping depends on how the delay information in the SDF file was created, and what type of analysis you are performing.

The timing system provides special handling for annotating incremental delays. These delays typically represent plus or minus offsets due to crosstalk effects. Incremental delay annotation to the Tempus System software can be done by:

- Importing an incremental SDF file (SDF has an internal `INCREMENT` keyword) using the `read_sdf` command.
- Tcl sourcing a file of `set_annotated_delay -net -delta_only` constraints.

The incremental delay annotations can be viewed in the `report_timing` report by adding the `incr_delay` option to the `report_timing -format list`, or to the `report_timing_format` attribute.

Parameters

<code>-help</code>	Prints out the command usage.
--------------------	-------------------------------

<code>-continue_on_error</code>	Continues to read the file if an error occurs. By default, when an error occurs, the <code>read_sdf</code> command stops reading the file. Use this parameter to attempt to continue reading the file, if possible. Note: Use caution if you continue, because some annotations could be missing due to the errors. Use the <code>report_annotated_parasitics</code> command to find missing annotations. If the file is corrupted, obtain a new SDF file.
<code>-early_sdf_field {min typ max}</code>	Annotates the early delay from the specified SDF field. In single-corner mode, all setup and hold analysis uses max delays. The software ignores any min/early delay information. In best-case worst-case mode, use this parameter to specify which SDF field to use for hold analysis. In on-chip variation mode, the software uses the early delay for calculation of fast paths.
<code>-ilm_filter</code>	Ignores ILM-related errors. By default, the <code>read_sdf</code> command does not ignore errors reported due to missing arcs in core ILM.
<code>-incremental</code>	Increments the total delay without affecting the delta delay. By default, when the SDF file contains the INCREMENT delay type, the <code>read_sdf</code> command will perform an adjustment on the delta delay slot which models SI cross-talk push-out/pull-in effects. When this option is used, the INCREMENT delays will be applied against the static base delay values instead.

<code>-late_sdf_field {min typ max}</code>	Annotates the late delay from the specified SDF field. In single-corner mode, use this parameter to specify which of the SDF triplet values to annotate for both setup and hold checks. In best-case worst-case mode, use this parameter to specify which SDF field to use for setup analysis. In on-chip variation mode, the software uses the late delay for the calculation of slow paths.
<code>-overwrite_incremental_delay</code>	When annotating an incremental SDF file, replaces any pre-existing delta delays with the new SDF values. The total delay will be equivalent to the original base delay, plus the new delta delay. If the delays in the incremental SDF file represent crosstalk delay push-outs from a signal integrity analysis, use the <code>-overwrite_incremental_delay</code> parameter to ensure that any stale data from a previous analysis is removed. By default, when an incremental SDF file (SDF has an internal <code>INCREMENT</code> keyword) is annotated, the delays are added to the base delay, and also stored separately as delta delays. If an additional incremental SDF file is annotated, the software adds the existing base and delta delays with the new values.
<code>-path <i>instanceName</i></code>	Specifies the instance in the design to which the specified SDF file should be applied.
<code>-persistent</code>	Keeps the delays from certain SDF files persistently in use during various steps of the timing optimization . Use this parameter to support pre-timed structures, such as clock meshes.
<code>-report_summary</code>	Outputs the summary information of annotated delays.
<code>-scale <i>float</i></code>	Overrides the automatic scaling of SDF delays to the library units by the value given. To disable all scaling, use a value of 1.0.

<code>-sdf_field {min typ max}</code>	Annotates the delay from the specified SDF slot. In single-corner and best-case worst-case modes, the software uses this value for both setup and hold analysis. In on-chip variation mode, the software uses the same value from the specified SDF slot for both the early and late delays of the specified arc.
<code>sdf_file_name</code>	Specifies the name of the SDF file that has the back annotation data.
<code>-strict_cond_matching</code>	Annotates only the conditions that are an exact syntax-to-syntax match between the SDF file and the <code>.lib</code> file. <i>Default:</i> Uses looser conditional matching rules between the <code>.lib</code> and SDF arc specifications.
<code>-view viewName</code>	Annotates the specified analysis view(s) with the delays from the SDF file. You can use this parameter only when you are in multi-mode multi-corner analysis mode.

Examples

- The following command annotates delay information from the SDF min field in to the min/early slots, and maps the SDF max field data to the max/late delay slots:

```
read_sdf sdf_file_name
```

Given the following SDF, the default annotation will be:

```
(INTERCONNECT C1/Y RS/CK (0.123:0.456:0.789) (0.123:0.456:0.789))
```

- In single-corner analysis mode, a delay of 0.789 ns is annotated to the max delay slot.
 - In best-case worst-case mode, a delay of 0.123 ns is annotated to the min delay slot, and a value of 0.789 ns is placed in the max delay slot.
 - In on-chip variation mode, a delay of 0.123 is used for early delays, and a value of 0.789 ns is used for late delays.
- The following command annotates the SDF typ field to both the early and late delay slots:

```
read_sdf -sdf_field typ sdf_file_name
```
- The following command annotates the SDF typ field to the early delay slot, and the SDF max field

to the late delay slot:

```
read_sdf -early_sdf_field typ -late_sdf_field max sdf_file_name
```

- The following command annotates the SDF typ field to the late delay slot. The early delay slot is annotated with the default min SDF field:

```
read_sdf -late_sdf_field typ sdf_file_name
```

read_spef

```
read_spef
[-help]
file_name_list
[-decoupled]
[-extended]
[-idx]
[-keep_star_node_locations]
[-rc_corner list_of_rc_corners]
[-scale_rc]
[-skip_star_node_locations]
[-spef_field integer_list]
[-via_variation_file via_variation_file]
[-wire_variation_file wire_variation_file]
```

Loads resistors and capacitors for the interconnects in SPEF into the Tempus database to calculate delays or build a timing graph. Use this command to read in a SPEF file generated by a third-party extraction tool.

You can use this command to load a SPEF file, which is compressed (.gzip) format.

Note: This command supports multi-threaded SPEF reading scalable upto a maximum of four CPUs. The number of CPUs can be specified using the standard use model of Tempus.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>read_spef</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man read_spef</code> .
-decoupled	Grounds the coupling capacitances in the SPEF file and merges the capacitances on the same node. This parameter can be used only for static timing analysis and cannot be used for SI analysis.
-extended	Enables the reading of “\$llx=<value1> \$lly=<value2> \$urx=<value3> \$ury=<value4> \$LAYER=<number>” to set the layer number for nodes of a resistance from Quantus extended SPEF file. It also reads in extended *LAYER_MAP section, if it is present. This parameter can also read in “\$l=<length> \$w=<width> \$si_w=<swidth> \$lvl=<number>” to set the width, silicon width, or layer for nodes of a resistance from StarRC extended SPEF file.

<i>file_name_list</i>	Specifies a SPEF file or list of SPEF files as input for flat chip or hierarchical SPEF stitching respectively.
-idx	Enables Inter-Die Extraction (IDX) SPEF reading. IDX SPEF models the Inter-Die capacitive impact in the form of coupling and ground capacitances. Individual die and IDX SPEFs need to be extracted by Quantus and in the extended SPEF (xSPEF) format. The -extended parameter is also required to be specified to read the xSPEF format. The software also supports multiple IDX SPEF reading. Flat die-level SPEFs need to be specified along with IDX SPEFs. With the -idx parameter, die-level and IDX SPEFs can be specified in any order.
- keep_star_node_locations	Enables the reading of the *N statements in the SPEF file. The *N statements define the location of the RC nodes.
-rc_corner list_of_rc_corners	Annotates the parasitics to the predefined RC corners for multi-corner analysis. You can specify a list of RC corners to be annotated. If you want to use SPEF information when calculating delays in multi-mode multi-corner analysis (MMMC) mode, you must annotate the parasitics for all RC corners in the design. A few examples are provided below to explain different scenarios of specifying rc corners are their corresponding corner indices and SPEF files. <pre>read_spef -rc_corner {rcCorner1 rcCorner2 rcCorner3 rcCorner4 rcCorner5} -spef_field {1 2 3 4 5} rc-spef.gz</pre> This means that SPEF file can contain parasitics from N RC corners and names of RC corners in the RC corner list map to the index fields specified using the -spef_field option as shown above. Assuming that the SPEF file, rc-spef.gz has RC fields from the specified five RC corners, the above command would be interpreted as follows: 1st field in SPEF maps to RC corner, rcCorner1 2nd field in SPEF maps to RC corner, rcCorner2 3rd field in SPEF maps to RC corner, rcCorner3 4th field in SPEF maps to RC corner, rcCorner4 , and 5th field in SPEF maps to RC corner, rcCorner5 <pre>read_spef -rc_corner {rc_max rc_min} -spef_field {2 5} rc-spef.gz</pre> Assuming rc-spef.gz in above example has RC fields from "N" RC corners, the above command would read SPEF data for two RC

	corners only and would be interpreted as follows: 2nd field in SPEF maps to RC corner, <code>rc_max</code> 5th field in SPEF maps to RC corner, <code>rc_min</code> • <code>read_spef -rc_corner {rcCorner1 rcCorner2 rcCorner3} -spef_field {1 1 3} rc-spef.gz</code> Assuming <code>rc-spef.gz</code> in the above example has RC fields from N RC corners, the above command would read SPEF data for 3 RC corners only and would be interpreted as follows: 1st field in SPEF maps to RC corner, <code>rcCorner1</code> 1st field in SPEF also maps to RC corner, <code>rcCorner2</code> 3rd field in SPEF maps to RC corner, <code>rcCorner3</code> • <code>read_spef -rc_corner {rcCorner1 rcCorner2 rcCorner3 rcCorner4 rcCorner5} -spef_field {1 2 3 4 5} {top.spef.gz block1.spef.gz block2.spef.gz}</code> In the above example, hierarchical design SPEF files are read in. It reads top level multi-field SPEF file followed by the multi-field SPEF files from <code>block1</code> and <code>block2</code>. Note: SPEF reading will not be triggered until SPEF files for all active RC corners are specified.
<code>-scale_rc</code>	Scales the SPEF read in for the specified corner as per the <code>postRoute_cap</code>, <code>postRoute_xcap</code>, and <code>postRoute_res</code> scale factors defined using the <code>create_rc_corner</code> and <code>update_rc_corner</code> commands.
<code>-skip_star_node_locations</code>	Ignores the *N statements in the SPEF file. The *N statements define the location of the RC nodes. Note: By default, the software ignores the *N statements while reading SPEF.
<code>-spef_field integer_list</code>	Specifies the field of the triplet values in spef to be loaded. Note: This parameter is relevant only when the <code>-rc_corner</code> parameter is specified.
<code>-via_variation_file via_variation_file</code>	Specifies the name of the file for modeling via variation. The contents of the file include all the via layer names with corresponding MEAN_SHIFT and STDDEV so that all the VIA resistance in SPEF can be mapped to their own variation multiplier. This option is used to specify the via_variation file only when the design has a single corner.

For example,

```
read_spef
    -rc_corner rcCornerName \
-via_variation_file viaVariationFileName
```

A sample via_variation file is provided below:

```
// corner_name : rcMax
// wildcard to cover default
object_type : design
delay_type : via
layer_name : *
area : 0.20 0.40 0.80
// no nominal for wildcard default
table_min_sigma : 0.80 0.90 0.95
table_max_sigma : 1.60 1.30 1.15
table_meanshift : 0.05 0.03 0.02
table_stdev : 0.10 0.05 0.02
// per via layer data
object_type : design
delay_type : via
layer_name : VIA1
Area : 0.0004 0.0008 0.0016
table_min_sigma : 0.80 0.90 0.95
table_max_sigma : 1.60 1.30 1.15
table_meanshift : 0.015 0.015 0.012
table_stdev : 0.214 0.150 0.117
object_type : design
delay_type : via
layer_name : VIA2
area : 0.0004 0.0008 0.0016
table_min_sigma : 0.80 0.90 0.95
table_max_sigma : 1.60 1.30 1.15
table_meanshift : 0.015 0.012 0.014
....
```

	<pre>..... table_stdev : 0.223 0.183 0.140</pre> Note: Each line in the file lists the basic components of the statistical variation approach. The values in the "area" line list all possible areas. In the above example, the area line lists three cases that can happen in the design. It can list different number of cases, for example one or four. The subsequent lines list the corresponding values matching to the areas defined in the area line.
<pre>-wire_variation_file wire_variation_file</pre>	When specified, the software loads the wire variation side file.

Examples

- The following command loads the SPEF file `TOPCHIP_SP.spef` for a flat chip methodology for RC corner, `corner1`:

```
read_spef -rc_corner corner1 TOPCHIP_SP.spef
```
- The following command loads multiple SPEF files for hierarchical SPEF stitching:

```
read_spef -rc_corner corner1 { PTN/results_conv/results_conv.spef
tdsp_core/tdsp_core/tdsp_core.spef PTN/TOPCHIP_SP/TOPCHIP_SP.spef }
```
- The following commands a) setup the appropriate scale factors for the corners `RCmax` and `RCmin` b) scale the SPEF read for the defined corners `RCmax` and `RCmin`:

```
=== MMMC setup ===

create_rc_corner -name RCmax -postRoute_cap 1.4 -post_route_xcap 1.4 -postRoute_res 1.4
create_rc_corner -name RCmin -postRoute_cap 0.8 -post_route_xcap 0.8 -postRoute_res 0.8
...

=== run script===
...

read_spef -rc_corner RCmax typSPEF.spef -scale_rc
read_spef -rc_corner RCmin typSPEF.spef -scale_rc
```
- The following command loads a SPEF file `pnta-spef.gz` that has RC fields from 5 RC corners:

```
read_spef -rc_corner {rcCorner1 rcCorner2 rcCorner3 rcCorner4 rcCorner5} -spef_field {1
2 3 4 5} pnta-spef.gz
```

The above command will be interpreted as follows:

1st field in SPEF maps to RC corner rcCorner1
2nd field in SPEF maps to RC corner rcCorner2
3rd field in SPEF maps to RC corner rcCorner3
4th field in SPEF maps to RC corner rcCorner4
5th field in SPEF maps to RC corner rcCorner5

- The following command loads a SPEF file `pnta-spef.gz` that has RC fields from N RC corners:

```
read_spef -rc_corner {rc_corner1 rc_corner2} -spef_field {2 5} pnta-spef.gz
```

The above command will read SPEF data for 2 RC corners only and will be interpreted as follows:

2nd field in SPEF maps to RC corner rc_corner1
5th field in SPEF maps to RC corner rc_corner2

- The following command loads a SPEF file `pnta-spef.gz` that has RC fields from N RC corners:

```
read_spef -rc_corner {rcCorner1 rcCorner2 rcCorner3} -spef_field {1 1 3} pnta-spef.gz
```

The above command will read SPEF data for 3 RC corners only and will be interpreted as follows:

1st field in SPEF maps to RC corner rcCorner1
1st field in SPEF maps to RC corner rcCorner2 as well.
3rd field in SPEF maps to RC corner rcCorner3

- The following command loads hierarchical design SPEF files. The software reads the top level multi-field SPEF file followed by the multi-field SPEF file from `block1` and `block2`:

```
read_spef -rc_corner {rcCorner1 rcCorner2 rcCorner3 rcCorner4 rcCorner5} -spef_field {1  
2 3 4 5} {top.spef.gz block1.spef.gz block2.spef.gz}
```

[-view_map_file view_map_file]  
[dir_name]
```

Reads the timing context of a block specified in the input directory.

Note: The `read_timing_context` command is not supported in DSTA. The context written from top level DSTA can be read in lower level STA runs.

Parameters

<code>-help</code>	Prints out the command usage.
<code><i>dir_name</i></code>	Specifies the name of the input directory to load context data.
<code>-clock_mapping_file</code> <code><i>clock_mapping_file</i></code>	Specifies the clock mapping file. This file contains user-provided information to guide clock mapping. The software inferred clock mapping will be overwritten by the user-specified clock mapping defined in the <code>clock_mapping_file</code> file.
<code>-instances</code> <code><i>instance_list</i></code>	Specifies the list of instances for which analysis needs to be performed. The instances provided should belong to a single cluster file, otherwise context reading will error out. When this parameter is not specified, the software performs context analysis of all the instances (belonging to a cluster) of a design.
<code>-</code> <code>skip_interface_paths</code>	Skips the interface paths.
<code>-view_map_file</code> <code><i>view_map_file</i></code>	Specifies the view mapping file. This file contains user-specified information to guide view mapping using the <code>set_timing_context_view_mapping</code> command. In case of MMC flow with different view names in block and top STA, the equivalent block and top view names can be specified under the <code>view_map_file</code> file.

Examples

- The following command will read context models of all the instances of the `tdsp_core` design that are part of one cluster:

```
read_timing_context context
```
- The following command will read context models corresponding to the `tdsp_core_inst1` instance of the `tdsp_core` design:

```
read_timing_context context -instance {tdsp_core_inst1}
```
- The following command will read merged context model corresponding to the `tdsp_core_inst1` and `tdsp_core_inst2` instances of `tdsp_core` design - provided that both the instances are part of a single cluster:

```
read_timing_context context -instance {tdsp_core_inst1 tdsp_core_inst2}
```

The command will error out if these instances are part of different clusters.
- The following command will read context model of `tdsp_core` design with user-defined clock mapping and view mapping files:

```
read_timing_context context -clock_mapping_file clkMap.txt -view_map_file viewMap.txt
```

Related Commands

- `write_timing_context`
- `set_timing_context_view_mapping`
- `report_timing_context_clock_mapping`
- `compare_timing_context`

read_twf

```
read_twf  
[-help]  
[filenames]  
[-cell string]  
[-prefix string]  
[-quiet]  
[-reset]  
[-scope string]  
[-skip_constant]  
[-skip_timing_window]  
[-strip_prefix string]  
[-verbose]  
[-view string]
```

Reads the external timing window file (TWF) for noise (Signal Integrity) and power calculation (Common Power Engine - CPE). This file is used to obtain clocks, constants, external load, slews, timing windows, and slack information. The external TWF specification is optional. In the absence of a TWF, this information is automatically derived using the Common Timing Engine (CTE), if timing constraints are read.

Note: If the `VOLTAGE_THRESHOLD` construct is missing from the TWF file header, the values 10 and 90 are automatically assigned as the minimum and maximum threshold values, respectively. For example:

```
VOLTAGE_THRESHOLD (10 90)
```

Parameters

<code>-help</code>	Prints out the command usage.
<code>-cell <i>string</i></code>	Specifies the master cell for the timing window file.
<code><i>filenames</i></code>	Specifies the names of the timing window files.
<code>-prefix <i>string</i></code>	Adds a prefix to the net or pin name.
<code>-quiet</code>	Skips information and warning messages.
<code>-reset</code>	Clears the previously read TWF files.
<code>-scope <i>string</i></code>	Specifies the scope for the given hierarchical timing window file.
<code>-skip_constant</code>	Skips constant processing.
<code>-skip_timing_window</code>	Skips timing windows processing.
<code>-strip_prefix <i>string</i></code>	Removes hierarchical path name.
<code>-verbose</code>	Prints the command progress details.
<code>-view <i>string</i></code>	Specifies the view for the timing window file.

Examples

- The following command reads the timing window file TW.in for the view 'view01', while skipping the constant processing from the timing window file:

```
tempus> read_twf TW.in -skip_constant -view view01
```

- The following command clears the previously read TWF file:

```
tempus> read_twf -reset
```

Related Commands

- `write_twf`

report_analysis_coverage

```
report_analysis_coverage
[-help]
[pin | port]
[-check_type check_type_list]
[-exclude_untested reason_list]
[-include_dynamic_checks]
[-include_parallel_check_arcs]
[-include_when_cond]
[-max_paths {type integer}]
[-nworst integer]
[-retime {aocv | ssta | path_slew_propagation | aocv_path_slew_propagation}]
[-sort {pin | refpin | checktype | slack | reason}]
[-tcl_list]
[-unsorted]
[-verbose check_status_list]
[-view view_name]
[> <filename[.gz]>]
[>> <filename[.gz]>]
```

Provides information about timing checks in the design.

For each type of timing check, the command reports the number of checks that meet constraints, violated constraints, or that are untested in the SUMMARY section of the report. The DETAILS section includes information about the signal pin, reference pin, check type, slack, and the reason for being untested.

When `timing_report_group_based_mode` is set to `true`, this command will report a check at end points for all the clocks. In verbose mode, the "clock" column will be displayed.

 Use `check_timing` to look for missing constraints.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

```
{> | >>} file_name
```

When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it.

When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file.

The *filename* parameter must be the last argument in the list. The *filename* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together.

Note: To write a compressed report, add the `.gz` extension to the file name.

Default: Report is displayed on standard output without being saved.

`-check_type check_type_list`

Reports checks that as specified in the *check_type_list*.

Valid check types are:

- clock_gating_hold
- clock_gating_pulse_width
- clock_gating_setup
- clock_period
- clock_separation
- data_hold
- data_setup
- external_delay:
- hold
- no_change_hold
- no_change_setup
- path_delay
- pulse_width
- recovery
- removal
- setup
- skew
- time_borrow

Note: If there are no specified timing checks in the design, the report shows "No timing checks found."

Default: All (all types of check(s) are reported)

<code>-exclude_untested {reason_list}</code>	Excludes from the report endpoints that are unconstrained due to a specific reason. Valid reasons are: • <code>const</code>: Constant reaching signal/reference pin of any timing check. • <code>false_path</code>: Path disabled due to <code>set_false_path</code>. • <code>no_endpoint_clock</code>: Missing clock at the reference pin of the timing check. • <code>no_startpoint_clock</code>: Missing clock at the signal pin of the timing check. This may happen if the clock signal does not reach the launching register. • <code>unknown</code>: None of the known reasons are identified for an untested path. • <code>user_disable</code>: Checks are disabled due to <code>set_disable_timing</code>.
<code>-include_dynamic_checks</code>	Reports the dynamic checks (<code>data_to_data</code>, <code>path_delay</code>) on pins that are constrained by <code>set_data_check</code>, <code>set_max_delay</code>, or <code>set_min_delay</code> constraints. By default, these checks will not be reported and the command only reports the pins constrained by all library checks, <code>set_output_delay</code> or inferred clock gating checks. The dynamic checks, such as <code>set_data_check</code> or <code>set_max_delay</code> are not reported by default, when <code>-include_dynamic_checks</code> parameter is not specified.
<code>-include_parallel_check_arcs</code>	Reports all the parallel check arcs that have been merged.
<code>-include_when_cond</code>	Reports the when condition of check arcs.
<code>-max_paths {type integer}</code>	Enumerates the specified number of worst paths in the design, regardless of the endpoint.
<code>-nworst integer</code>	Enumerates the specified number of paths for each endpoint.

<pre>-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation}</pre>	Reanalyzes the set of paths using the specified method.
<pre>pin port</pre>	Limits the report to timing checks on specified pins or ports.
<pre>-sort {pin refpin checktype slack reason}</pre>	Sorts the checks by the specified option while reporting detailed information using the <code>-verbose</code> option. The <code>-sort</code> parameter does not change the order of the columns. The valid sort options are: <code>pin</code>, <code>refpin</code>, <code>checktype</code>, <code>slack</code>, <code>reason</code> When sorting by pin name, if the pin names are the same, the software then attempts to sort the checks by slack value. If the slack values are the same, the software attempts to sort by timing check type. When sorting by timing check type, if the check types are the same, the software then attempts to sort by slack value. If the slack values are the same, the software attempts to sort by pin name. When sorting by slack, if the slack values are the same, the software then attempts to sort the checks by pin name. If the pin names are the same, the software attempts to sort by timing check type. When you sort by <code>slack</code>, the slack value is reported in order of least negative to most negative (worst slack last). You can use the following commands for debugging purposes and to improve readability of the report: <pre>report_analysis_coverage -verbose untested - sort reason report_analysis_coverage -verbose violated - sort slack</pre> Default: By default, checks are sorted by slack value (<code>slack</code>).

<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-unsorted</code>	Reports unsorted slacks with untested end points at the end of the report.
<code>-verbose check_status_list</code>	Limits the detailed information to checks as per the specified status. The valid status types are: <code>met</code>, <code>violated</code>, and <code>untested</code>. • <code>met</code>: Shows as a positive value in the Slack column. • <code>violated</code>: Shows as a negative value in the Slack column. • <code>untested</code>: Shows as UNTESTED in the Slack column and the reason is given in the Reason column. The Reason column will be blank when a Slack number is displayed - this indicates the check has been tested. You can reduce the number of lines in the DETAILS section by filtering out the met checks, as shown in the example below: <pre>report_analysis_coverage -verbose {violated untested}</pre> Note: The <code>-verbose</code> parameter supports multi-threading.
<code>-view view_name</code>	Generates a timing check report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner analysis mode.

Examples

- The following command shows the report output for pulse width checks for the specified view:

```
tempus > report_analysis_coverage -check_type pulse_width -view func_slow_RCMAX
```

```
-----
                        TIMING CHECK COVERAGE SUMMARY (Analysis View:  func_slow_RCMAX)
-----
```

Check Type	No. of Checks	Met	Violated	Untested
PulseWidth	1541	1096 (71%)	42 (2%)	403 (26%)

- The following command shows the report output for the specified view port:

```
tempus > @report_analysis_coverage port_pad_data_out
```

```
-----
                        TIMING CHECK COVERAGE SUMMARY
-----
```

Check Type	No. of Checks	Met	Violated	Untested
ExternalDelay (Early)	16	16 (100%)	0 (0%)	0 (0%)
ExternalDelay (Late)	16	0 (0%)	16 (100%)	0 (0%)

- The following command reports checks for graph-based analysis (GBA) paths:

```
tempus > report_analysis_coverage -retime path_slew_propagation
```

```
-----
                        TIMING CHECK COVERAGE SUMMARY
-----
```

Check Type	No. of Checks	Met	Violated	Untested
ClockPeriod	6	6 (100%)	0 (0%)	0 (0%)
ExternalDelay (Early)	29	26 (89%)	0 (0%)	3 (10%)
ExternalDelay (Late)	29	0 (0%)	26 (89%)	3 (10%)
Hold	1741	1486 (85%)	37 (2%)	218 (12%)

report_analysis_summary

```
report_analysis_summary  
[-help]  
[-csv string]  
[-merged_views]  
[-retime {path_slew_propagation | aocv_path_slew_propagation}]  
[-retime_mode {exhaustive}]  
[-view viewName]  
[> <filename[.gz]>]  
[>> <filename[.gz]>]  
[-early | -late ]  
[-expanded_summary_clocks | -merged_groups]
```

Generates timing slack summary reports for specified analysis view(s). This command categorizes the slack summary in terms of groups - In2reg, Reg2reg, Reg2Out, and In2Out. A column "ALL" is displayed that regroups in2reg, in2out, reg2reg, and reg2out details.

By default, the slack is categorized in terms of worst negative slack (WNS), total negative slack (TNS), and the total number of violations in group-based mode.

The `report_analysis_summary` command is supported in path-based analysis (PBA) mode.

Parameters

<code>-help</code>	Prints out the command usage.
<code>{> >>} filename</code>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
<code>-csv string</code>	Specifies the name of the CSV output file.
<code>-early</code>	Generates report for hold analysis mode for early paths.
<code>-expanded_summary_clocks</code>	Generates report in terms of each possible clock domain pair separately.
<code>-late</code>	Generates report for setup analysis mode for late paths.
<code>-merged_groups</code>	Merges all the clock groups for a consolidated timing summary.
<code>-merged_views</code>	Generates a merged report across all the views.
<code>-retime {path_slew_propagation aocv_path_slew_propagation}</code>	Reanalyzes the defined set of paths using the specified method. By default, the timing report shows a maximum of 2 million paths for retime PBA analysis.
<code>-retime_mode {exhaustive}</code>	Reanalyzes the specified set of paths using the specified retime mode.
<code>-view viewName</code>	Generates report for the specified analysis views only. By default, all the active views are analyzed.

Examples

- The `report_analysis_summary` command shows the following report output:

```
tempus> report_analysis_summary

report_analysis_views
-help
[-type {all | setup | hold | active}]
```

Generates a hierarchical report of the current multi-mode multi-corner configuration. By default, the `report_analysis_views` command generates a report of all defined views in the design. Use the `-type` parameter to generate a report on a specific type of analysis view.

Use this command after creating analysis views (`create_analysis_view`), and setting active setup and hold views (`set_analysis_view`) for the design.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>report_analysis_views</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man report_analysis_views</code> .
-type {all setup hold active}	Specifies the type of report to generate. • active: Generates a report of all active setup and hold views in the design. • all: Generates a report of all defined views in the design, including those that are currently inactive. • hold: Generates a report of all active hold views in the design. • setup: Generates a report of all active setup views in the design. <i>Default:</i> all

Examples

- The following command reports all the defined views in the design:

```
tempus > report_analysis_views
Multi-Mode Analysis View Report
```

```

report_annotated_assertions

```
report_annotated_assertions
-type {load | transition}
[-list_annotated]
[-list_non_annotated]
[-view viewName]
[-max_lines number]
[-min | -max | -min_max]
obj_list
[{> | >>} file_name]
```

Reports information for annotated assertions, set using the `set_load` or `set_annotated_transition` command, according to the specified assertion type. You can select load or transition reporting.

Note: The `report_annotated_assertions` command is now obsolete. This command will continue to be supported in the current release, but will be removed in the next major release of the software.

Parameters

<code>{> >>} file_name</code>	Writes the report to the specified file name. When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified filename. If the file already exists, the software concatenates the report to the end of the file.
<code>-list_annotated</code>	Lists the detailed information for the specified assertion types.
<code>-list_non_annotated</code>	Lists information for non-annotated assertions.

<code>-min -max -min_max</code>	Specifies to report minimum, maximum, or both values of the specified assertion type. When input assertions are applied using both <code>-min</code> and <code>-max</code> parameters, you can specify the <code>-min_max</code> parameter to report both the assertion values. In this case, you do not need to specify this command twice, that is, separately with <code>-min</code> and <code>-max</code> parameters. <i>Default:</i> max
<code>-max_lines number</code>	Controls the number of output lines reported by <code>-list_annotated</code> or <code>-list_non_annotated</code> parameter. By default, the specified net, pin, or port names are reported.
<code>obj_list</code>	Specifies the list of nets, pins, or ports to be reported.
<code>-type {load transition}</code>	Specifies the assertion type, load or transition, to be reported.
<code>-view viewName</code>	Reports the annotations for the specified analysis view. In multi-mode multi-corner timing analysis mode, annotations are reported for the specified mode or corner.

Examples

- The following command reports all the transition annotated assertions for the specified view:

```
tempus > report_annotated_assertions -type transition -list_annotated -view
func_slow_RCMAX
```

Analysis View: func_slow_RCMAX

Assert type	Total	Annotated	Not Annotated	Percentage Annotated
Transition (Max)	29097	0	29097	0.000

- The following command reports details of both the minimum and maximum values of the specified assertion type:

```
tempus > report_annotated_assertions -type load -list_non_annotated -min_max -
max_lines 5 -view scan_slow_RCMAX
```

Analysis View: scan_slow_RCMAX

Load (Min:Max) Non Annotated				
NetName				
tdigit[7]				
tdigit[6]				
tdigit[5]				
tdigit[4]				
tdigit[3]				
Assert type	Total	Annotated	Not Annotated	Percentage Annotated
Load (Min:Max)	8415	0	8415	0.000

Related Commands

- `set_load`
- `set_annotated_transition`

report_annotated_check

```
report_annotated_check
[-help]
[-check_type check_type_list]
[-max_line number]
[instance_list]
[-list_annotated]
[-list_non_annotated]
[-view viewName]
[> | >> filename[.gz] | -tcl_list]
```

Reports coverage of annotated timing checks.

Parameters

-help	Prints out the command usage.
-check_type <i>check_type_list</i>	Allows you to specify the check type. The valid check types are <code>setup</code> , <code>hold</code> , <code>pulse_width</code> , <code>clock_period</code> , <code>clock_gating_setup</code> , <code>clock_gating_hold</code> , <code>clock_gating_pulse_width</code> , <code>data_setup</code> , <code>data_hold</code> , <code>recovery</code> , <code>removal</code> , <code>clock_separation</code> , <code>no_change_setup</code> , <code>no_change_hold</code> , and <code>skew</code> .

> <i>filename</i>	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <i>filename</i> parameter must be the last argument in the list. The <i>filename</i> and <i>-tcl_list</i> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the .gz extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
<i>instance_list</i>	Specifies instance names for which annotations of check arcs are to be reported.
<i>-list_annotated</i>	Lists the detailed annotation information for the following timing checks: • setup • hold • recovery • removal • pulse-width • nochange-setup • clock-period • skew Note: If the software is in multi-mode multi-corner timing analysis mode, you need to specify the <i>-view</i> parameter.

<code>-list_non_annotated</code>	Lists the timing checks that do not have annotated delay information. The software checks for the following timing checks: • setup • hold • recovery • removal • pulse-width • nochange-setup • clock-period • skew Note: If the software is in multi-mode multi-corner timing analysis mode, you need to specify the <code>-view</code> parameter.
<code>-max_line <i>number</i></code>	Controls the number of output lines reported by the <code>-list_annotated</code> or <code>-list_non_annotated</code> parameter.
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-view <i>viewName</i></code>	Reports coverage of annotated timing checks for the specified analysis view. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode. <i>Default:</i> Reports annotated timing checks for the default analysis view.

Examples

- The following command reports the setup timing checks that do not have annotated delay information:

```
tempus > report_annotated_check -check_type setup -list_non_annotated -max_line 6 -
```

```
view scan_slow_RCMAx
Analysis View: scan_slow_RCMAx

report_annotated_delay

```
report_annotated_delay
[-help]
[-ignore_tied_net_arcs]
[-list_annotated]
[-list_non_annotated]
[-view viewName]
[-max_line number]
[{> | >>} filename[.gz] | -tcl_list]
[pin_port_list]
```

Reports coverage of annotations on a design. These annotations include SDF delay arc annotations. Besides SDF annotations, the command also reports annotations that are set using the `set_annotated_delay` command.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>report_annotated_delay</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_annotated_delay</code> .
> >> filename	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <code>filename</code> parameter must be the last argument in the list. The <code>filename</code> and <code>-tcl_list</code> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.

<code>-ignore_tied_net_arcs</code>	Ignores timing arcs of power and ground nets.
<code>-list_annotated</code>	Lists detailed annotation information for the following annotated arcs: • annotated internal net arcs • annotated input port arcs • annotated output port arcs • annotated cell arcs
<code>-list_non_annotated</code>	Lists the arc information for the non-annotated arcs corresponding to the following types of arcs: • non-annotated internal net arcs • non-annotated input port arcs • non-annotated output port arcs • non-annotated cell arcs
<code>-max_line <i>number</i></code>	Controls the number of output lines reported by <code>-list_annotated</code> or <code>-list_non_annotated</code> parameter.
<code>pin_port_list</code>	Specifies the pin/port list for which annotated delay is to be reported.
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-view <i>viewName</i></code>	Generates the report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

- The following command reports the status of annotation for cell arcs, internal net arcs, net arcs

from primary inputs, and net arcs to primary outputs, and all the timing arcs separately.

```
tempus > report_annotated_delay -view scan_slow_RCMIN -list_annotated -
ignore_tied_net_arcs
```

Analysis View: scan_slow_RCMIN

Delay Arc Type	Total	Annotated	Not Annotated	Percentage Annotated
Cell arcs	38365	0	38365	0.000000
Input net arcs	141	0	141	0.000000
Internal net arcs	20019	0	20019	0.000000

report_annotated_parasitics

```
report_annotated_parasitics
[-help]
[-include_nets <string>]
[-include_nets_file <string>]
[-view {viewName}]
[> {write_fileName}]
[>> {append_fileName}]
[[-list_annotated] [-broken_nets] [-list_extra_pin_net] [-floating_nets] [-no_driver_nets] [-unloaded_nets]
    [-list_not_annotated] [-list_zero_cap_net] [-real_nets] [-supply_nets] [-max_missing
{max_missing_int}]]]
```

Reports the back-annotated parasitics of the design. By default only summary report is generated. The software groups all the nets by net-types and annotation-status (annotated or not-annotated).

Parameters

-help	Outputs a brief description that includes type and default information for the <code>report_annotated_parasitics</code> parameters. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man report_annotated_parasitics</code>.
>> {append_fileName}	Writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. Note: The file name must be the last argument in the list. <i>Default:</i> Report is displayed on standard output without being saved.
-broken_nets	Reports broken nets in the design.
-list_extra_pin_net	Generates a list of nets that have extra pins in the SPEF but not in the Verilog.
-floating_nets	Generates a list of floating nets.

<code>-include_nets_file string</code>	Accepts a file name, which contains a list of net names, as input. When this parameter is specified, the parasitic annotation summary is provided only for the listed nets. The net names in the file can be specified as one net per line.
<code>-include_nets string</code>	Specifies a list of net names for which annotation summary is required.
<code>-list_annotated</code>	Generates a list of annotated nets.
<code>-list_not_annotated</code>	Generates a list of not annotated nets.
<code>-list_zero_cap_net</code>	Generates a list of zero capacitance nets.
<code>-no_driver_nets</code>	Lists all the terminal nets that have no driver.
<code>-real_nets</code>	Lists all real nets.
<code>-supply_nets</code>	Lists all supply nets.
<code>-max_missing {max_missing_int}</code>	Limits the number of missing annotations to the number specified. <i>Default: 1000</i>
<code>-unloaded_nets</code>	Lists all the terminal nets that have no load.
<code>-view viewname</code>	Reports the back-annotated parasitics for the specified analysis view. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode. <i>Default: Reports against the default analysis view</i>
<code>> {write_fileName}</code>	Writes the report to the specified file name. If the file already exists, the software overwrites it.

Examples

- The following command generates a list of annotated and not-annotated nets:

```
tempus > report_annotated_parasitics -broken_nets -view func_slow_RCMAx -
supply_nets -max_missing 10 -floating_nets

# list syntax: type: net_name [nrCap Cap nrXCap XCap nrRes Res]
# unit: pF, Ohm
# No annotated supply net.
```

```
# No annotated dummy net (floating).
```

```
# Summary of Annotated Parasitics:
```

Net Type	Count	Annotated (%)	Not Annotated (%)
total	8751	8408 96.08%	343 3.92%

report_aocv_derate

```
report_aocv_derate
[-help]
[-check_global_derating]
[-clock]
[-data]
[-list_cell_not_annotated]
[-mesh]
-out_file string
[-voltage float]
[-design | -cell string ] [ {-delay_corner <string> [-power_domain string] } | -max | -min]
[-early | -late]
[-rise | -fall]
```

Reports the AOCV derating tables from AOCV libraries. The command generates the output report in AOCV library format.

Parameters

<code>-help</code>	Prints out command usage.
<code>-cell <i>string</i></code>	Reports the table for the specified library cell name. You can specify a regular expression corresponding to library cell names.
<code>-check_global_derating</code>	Reports the list of cells for which derating table or global derating table was not specified.
<code>-clock</code>	Reports derate tables read for clock paths.
<code>-delay_corner <i>string</i></code>	Reports the derating tables from the specified delay corner. For a MMMC design, if a delay corner specific table is read using the <code>create_library_set -aocv</code> command, that derating table is reported. Otherwise the default table is reported. For a non-MMMC design, no details are reported. The <code>-delay_corner</code> and <code>-min/-max</code> parameters are mutually exclusive.
<code>-data</code>	Reports derate tables read for data paths.
<code>-design</code>	Reports the default cell or net derating tables.
<code>-early -late</code>	Reports the early/late derating table.
<code>-list_cell_not_annotated</code>	Reports the list of cells for which derating table is not specified. This parameter reports an error when specified with <code>-voltage</code> , <code>-design</code> , or <code>-cell</code> parameters.
<code>-max</code>	Reports derate tables from max AOCV libraries.
<code>-mesh</code>	Reports derate tables read for mesh.
<code>-min</code>	Reports derate tables from min AOCV libraries.
<code>-out_file <i>string</i></code>	Specifies the name of the output file. When this parameter is specified, all the derate tables will be reported.
<code>-power_domain <i>string</i></code>	Reports derate tables from the specified power domain. This option should always be specified with delay corner.
<code>-rise -fall</code>	Reports the rise/fall table for specified transition.
<code>-voltage <i>float</i></code>	Reports derating tables for the specified voltage value.

Examples

Here are some examples.

- The following command reports derating tables for the specified cells:

```
tempus> report_aocv_derate -cell "BUF" -delay_corner default_emulate_delay_corner -  
out_file report.lib
```

```
#content of file "report.lib" :

Related Commands

- [timing_aocv_derate_mode](#)

report_boundary_model_constraints

report_boundary_model_constraints
[-help]

Reports the boundary model constraints that are applied using the `select_boundary_model_constraints` command.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

report_case_analysis

```
report_case_analysis
[-help]
[pins_and_ports_list]
[-all]
[-dir]
[-include_ref_name]
[-nosplit]
[-tcl_list]
[-verbose]
[-view view_name]
[> <filename[.gz]>]
[>> <filename[.gz]>]
[-propagated [-include_function]]
```

Generates a User Case Analysis table, which reports ports and pin that have a `set_case_analysis` constraint. These ports and pins are constant only for timing analysis. You can optionally generate a Logic Constant Value table, which reports ports and pins whose constant status is part of the design. Information from this table includes ports or pins with `set_logic` constraints (`set_logic_zero` and `set_logic_one`), netlist explicit constants, and output pins with constant output functions.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

<code>{> >>} filename</code>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <code>filename</code> parameter must be the last argument in the list. The <code>filename</code> and <code>-tcl_list</code> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
<code>-all</code>	Specifies that the Logic Constant Value table report pins or ports with <code>set_logic</code> constants, constants in the netlist, and output pins with a constant function. These output pins are from library cells or netlist modules.
<code>-include_function</code>	Displays the pin function of a pin. This must be specified with the <code>-propagated</code> parameter.
<code>-include_ref_name</code>	Displays the reference name of an instance in the report.
<code>-no_split</code>	Specifies that reports with long names will not be split into multiple lines. Note: The <code>-no_split</code> parameter works if <code>set_table_style -no_frame_fix_width</code> command is specified.
<code>-dir</code>	Specifies that the report include the direction of the pin or port, which is reported as input, output, or inout (internal pins may not have constant constraints).

<code>pins_and_ports_list</code>	Generates a report only for the pins and ports in the specified list. <i>Default:</i> Generates a report for all pins and ports in the design.
<code>-propagated</code>	Generates a report that includes all the constant pins, including pins with propagated constants. When specified, the report column header shows the constant values - the column header for constant values is <code>User case analysis value</code>. <i>Default:</i> Report shows pins specified with the <code>set_case_analysis</code> command.
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-verbose</code>	Generates a report in which each pin is listed on a separate line with a cause. If the pin is a propagated constant, a table is included that reports a chain of constants from an original cause to the reported pin. <i>Default:</i> All pins are reported in a table.
<code>-view view_name</code>	Generates a User Case Analysis table for the specified analysis view only. To specify this parameter, the software must be in multi-mode multi-corner (MMMC) analysis mode. <i>Default:</i> When in MMMC analysis mode, generates a table for all active analysis views

Examples

- The following command reports user case analysis values for all the analysis views:

```
tempus > report_case_analysis
Pin name      User      View Name
              case
              analysis
-----
tst_mode      0          scan_fast_RCMIN
tst_mode      0          scan_slow_RCMIN
```

tst_mode	0	func_slow_RCMAX
scan_en	0	scan_fast_RCMIN
scan_en	0	scan_slow_RCMIN

- The following command reports all the constant pins, including pins with propagated constants - and long names are not split into multiple lines:

```
tempus > report_case_analysis -propagated -no_split
```

```
-----
Pin name          Constant   View Name
                  value
-----
AB_IS/se_0/D      0          func_slow_RCMAX
AB_IS/se_0/RN     1          func_slow_RCMAX
AB_IS/se_0/SE     0          func_slow_RCMAX
AB_IS/se_0/SI     0          func_slow_RCMAX
AB_IS/se_0/SN     1          func_slow_RCMAX
AB_IS/se_1/D      0          func_slow_RCMAX
AB_IS/se_1/RN     1          func_slow_RCMAX
AB_IS/se_1/SE     0          func_slow_RCMAX
```

- The following command reports the Logic Constant Value table report pins or ports with set_logic constants, constants in the netlist, and output pins with a constant function. These output pins are from library cells or netlist modules.

```
tempus > report_case_analysis -all -no_split
```

```
-----
Pin name          Logic
                  constant
                  value
-----
AB_IS/t0/Z        0
AB_IS/t1/Z        1
AB_IS/dma_reg/SE  0
AB_IS/pre_reg[1]/SE 0
AB_IS/ECOlreg[2]/SE 0
```

- The following command reports the Logic Constant Value table of pins:

```
tempus > report_case_analysis -all -no_split -verbose
```

```
-----
Pin name          Logic
                  constant
                  value
-----
AB_IS/t0/Z        0
AB_IS/t1/Z        1
AB_IS/dma_reg/SE  0
```

Pin `tst_mode 0` view `scan_fast_RCMIN` is caused by `set_case_analysis 0` on pin `tst_mode`

Pin `tst_mode 0` view `scan_slow_RCMIN` is caused by `set_case_analysis 0` on pin `tst_mode`

Pin `tst_mode 0` view `scan_fast_RCMAX` is caused by `set_case_analysis 0` on pin `tst_mode`

- The following command reports user case analysis values for the specified view:

```
tempus > report_case_analysis -view scan_fast_RCMIN
```

```
-----
```

Pin name	User	View Name
	case	
	analysis	
	value	

```
-----
```

tst_mode	0	scan_fast_RCMIN
scan_en	0	scan_fast_RCMIN

```
-----
```

- The following command reports pins that include the direction of the pin - as input:

```
tempus> report_case_analysis -dir
```

```
-----
```

Pin name	Dir	User case
		Analysis value

```
-----
```

gscanmode	input	0
gscanenable	input	0

```
-----
```

- The following command reports all the constant pins, including pins with propagated constants:

```
tempus> report_case_analysis -propagated
```

```
-----
```

Pin name	Constant
	value

```
-----
```

clockandlatch/U8/TE	0
clockandlatch_dup1/U8/TE	1
clockandlatch_dup2/U8/TE	1
clockandlatch_dup3/U8/TE	0

```
-----
```

- The following command reports details of each pin separately. The pin `crclocklatch/U8/TE` is reported because of a `set_case_analysis 0` assertion on pin `gscan`:

```
tempus> report_case_analysis -propagated -verbose crclocklatch/U8/TE
```

Pin name	Constant Value

gscan	0
FE_OC36_gscan/I	0
FE_OC36_gscan/ZN	1
FE_OC37_gscan/I	1
FE_OC37_gscan/ZN	0
FE_OC35_gscan/I	0
FE_OC35_gscan/Z	0
crclocklatch/U8/TE	0

Related Commands

- `set_case_analysis`

report_cell_instance_timing

```
report_cell_instance_timing  
[-help]  
hinst_list  
[-clock_timing]  
[-tcl_list]  
[-view view_name]  
[> file_name]  
[>> file_name]  
[-early | -late]
```

Reports the following information about the timing context for all the pin and delay arcs of the specified instances:

- Arrival time
- Required time
- Slack
- Delays

Note: Internal pins (pins inside the instance boundary) are also reported.

This command uses the results of earlier timing analysis runs; therefore, you must run the [report_timing](#) command before using `report_cell_instance_timing`.

To analyze the setup (maximum) paths, you must use the `timing_analysis_check_type setup` attribute and run the `report_timing` command before using the `-late` parameter. Similarly, to analyze the hold (minimum) paths, you must use the `timing_analysis_check_type hold` attribute and run the `report_timing` command before using the `-early` parameter.

The `report_cell_instance_timing` timing report contains the following tables:

- The first table in the report contains information about the pins of the instance.
The propagated slew is the slew that is propagated to the pin, based on the slew propagation mode.
- The second table contains information about the arcs through the instance.
The slew out is the slew calculated at the arc output from the arc input slew, using the timing model.
- The third table, generated for sequential devices, contains information about the timing checks, if present, on the cell.
Only checks that are from the library are shown in this table. Automatic checks, such as clock gating setup and hold, are not reported.

The *Phase* column of each table can contain the following symbols:

- **D** indicates it is a data signal in the clock domain.
- **C** indicates it is a clock signal in the clock domain.
- **P** indicates it is a positive phase.
- **N** indicates it is a negative phase.
- **L** indicates it is a latency phase.
- Asterisk (*) indicates there is a timing exception associated with the signal.

Note: Currently, it is not possible to expand the asterisk to determine which exception is associated with the reported timing phase.

When the software is in multi-mode multi-corner timing analysis mode, the timing context information is reported for each active analysis view, with the view name listed in the *Phase* column.

Parameters

-help	Prints out the command usage.
{> >>} <i>filename</i>	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <i>filename</i> parameter must be the last argument in the list. The <i>filename</i> and -tcl_list parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the .gz extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
-clock_timing	Specifies to report slack for clock style checks.

<code>-early -late</code>	Reports the information for early (maximum) path (data hold/clock setup) or late (minimum) path (data setup/clock hold). <i>Default:</i> If you do not specify any of the parameters, the software uses the <code>-late</code> parameter.
<code>hinst_list</code>	Specifies a flat (non-hierarchical) cell instance or list of cell instances. Use curly braces ({}) to enclose the list and separate the instance names with white space.
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-view view_name</code>	Specifies the analysis view in which to query the object attribute.

Examples

- The following command reports information about the timing context of the specified cell instance:

```
tempus > report_cell_instance_timing FE_63_data_out_13 -view scan_fast_RCMIN
```

```
-----
                        Instance FE_63_data_out_13 of BUF_X32
-----

Pin      Dir      Propagated   Arrival   Required   Slack     Phase
                        Slew

-----
A ^       IN       0.067         5.567     38.295     32.728    m_clk(D) (P) (scan_fast_RCMIN)
A v       IN       0.055         5.528     38.214     32.687    m_clk(D) (P) (scan_fast_RCMIN)
-----

                        Instance FE_63_data_out_13 of BUF_X32
-----

Arc              Slew
-----

From    To    In    Out    Load  Delay              Phase
```

```
-----
A ^      Z ^      0.067    0.248    0.012    0.303    m_clk(D) (P) (scan_fast_RCMIN)
A v      Z v      0.055    0.140    0.012    0.384    m_clk(D) (P) (scan_fast_RCMIN)
-----
```

- The following example reports information about the timing context of instance seg1/u9:

```
tempus > report_cell_instance_timing seg1/u9
```

```
-----
Instance seg3/u14 of DFF
-----
```

Pin	Dir	Propagated Slew	Arrival	Required	Slack	Phase
CK ^	IN	0.062	0.621			CLK_W_3 (C) (P) *
CK v	IN	0.065				CLK_W_3 (D) (P) *
D v	IN	0.003	1.815	2.465	0.650	CLK_W_3 (D) (P)
CK ^	IN	0.062				CLK_W_3 (D) (N) *

```
-----
Instance seg3/u14 of DFF
-----
```

```
Arc Slew
-----
```

From	To	In	Out	Load	Delay	Phase
CK ^	QN ^	0.062	0.058	0.000	0.196	CLK_W_3 (C) (P) *
CK ^	QN v	0.062	0.041	0.000	0.236	CLK_W_3 (D) (P) *
CK ^	QN ^	0.062	0.000			CLK_W_3 (D) (N) *

```
-----
Instance seg3/u14 of DFF
-----
```

```
Pins Phase
-----
```

Check	Sig	Ref	Slack	Delay	Adjust	Sig	Ref
HOLD	D ^	CK ^	1.570	-0.129	0.000	CLK_W_3 (D) (P)	CLK_W_3 (C) (P) *
SETUP	D ^	CK ^	0.372	0.186	-2.000	CLK_W_3 (D) (P)	CLK_W_3 (C) (P) *

- If a constant is asserted or propagated to the instance pin, it is reported in the Phase column of the pin table, as shown in the following example:

```
tempus > report_cell_instance_timing p5042A
```

```
-----
Instance p5042A of MUX2HVTD1
-----
```

Pin	Dir	Propagated Slew	Arrival	Required	Slack	Phase
-----	-----	-----------------	---------	----------	-------	-------

```
-----
I0 ^   IN    0.032      0.127      8.583      8.455  EJ_TCK(D) (P)

report_clock_gating_check

```
report_clock_gating_check  
[-help]  
[obj_list]  
[-view view_name]  
[{> | >>} file_name]
```

Reports information of all or specific clock gating checks of the current design. If you specify a list of pins, cells, or clocks, the clock gating check information is reported for the specified objects only. If you use the `report_clock_gating_check` command without an object list, all clock gating check information is reported.

The `Type` column of the generated report (see examples below) can contain one of the following abbreviations:

- `I` indicates that the clock gating check is inferred.
- `L` indicates that the clock gating check is from the library (integrated clock gating check).

Parameters

<code>-help</code>	Prints out the command usage.
<code>obj_list</code>	Specifies a list of pins, instances, or clocks. A collection of these can also be specified. • Pin: Any pin of a clock gating cell can be specified and the check information will be reported for that pin. • Instance: Any instance name of a clock gating cell can be specified and the check information will be reported for that instance. • Clock: Only a clock at a given clock (reference) pin of a cell can be specified for reporting the check information. Check information about the clocks at enable (signal) pin cannot be reported. If the <code>obj_list</code> parameter is not specified, all the clock gating check points (inferred and library) of the current design are reported.

<code>-view view_name</code>	Specifies a view for which clock gating check is to be reported. The default is worst of all the views.
<code>{> >>} filename</code>	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file.

Examples

- The following command reports clock gating check details for the specified view:

```
tempus > report_clock_gating_check -view AV_bc_off
```

Clock Gating Check Report

Instance	Enable	Clock	Type	Level	Setup		Hold		View
					Rise	Fall	Rise	Fall	
sub_inst2/LCLK	EN	A	I	H	0.000	0.000	0.000	0.000	AV_bc_off

- The following command generates a clock gating check report for the specified collection:

```
tempus > report_clock_gating_check CLK
```

Clock Gating Check Report

Instance	Enable	Clock	Type	Level	Setup		Hold		View
					Rise	Fall	Rise	Fall	
sub_inst2/LCLK	EN	A	I	H	0.000	0.000	0.000	0.000	AV_wc_on

- The following command generates a clock gating check report for the current design:

```
tempus > report_clock_gating_check
```

The clock gating check report returned by this command is as follows:

Clock Gating Check Report

Instance	Enable	Clock	Type	Level	Setup		Hold		View
					Rise	Fall	Rise	Fall	
C_and_1	A	B	I	H	0.000	0.000	-	-	view1

report_clock_network_transitions

```
report_clock_network_transitions  
[-help]  
[-all]  
[-clock string]  
[-exclude_pins string]  
[-threshold float]  
[-verbose]  
[-view string]
```

Reports all the clock tree pins that have valid rise/fall maximum transition values.

This command generates reports on a per clock basis. For virtual clocks, no pins will be reported.

Parameters

-help	Prints out the command usage.
-all	Reports all the pins having a valid transition value.
-clock <i>string</i>	Specifies a list of clocks.
-exclude_pins <i>string</i>	Does not report the specified pins.
-threshold <i>float</i>	Does not report pins that have at least one of transition values (rise or fall) greater than the specified threshold value.
-verbose	Specifies to include the library cell information.
-view <i>string</i>	Specifies the name of the view.

Examples

The following command reports all pins along with the library cell information for the specified clock:

```
report_clock_network_transitions -clock m_digit_clk -verbose -view scan_slow_RCMAX -all
```

```
Clock: m_digit_clk
```

```
View: scan_slow_RCMAX
```

```
Clock Network:
```

	Pin	Lib Cell	Rise	
Fall				
	---	-----	----	---
-				
	TST_CONTROL_INST/p214748365A90/ZN	FrPK45_lib_v1.0/OAI21_X1	0.545	
0.193				
	m_digit_clk__L1_I0/A	FrPK45_lib_v1.0/BUF_X32	0.545	
0.193				
	m_digit_clk__L1_I0/Z	FrPK45_lib_v1.0/BUF_X32	0.460	
0.183				
	m_digit_clk__L2_I1/A	FrPK45_lib_v1.0/BUF_X16	0.462	
0.181				

report_clock_propagation

```
report_clock_propagation
[-help]
-clock clock_list
[-max_paths number of paths]
-to pin_port_list
[-verbose]
[-view viewName]
[> filename[.gz]]
[>> filename[.gz]]
```

This command provides the ability to determine clocks that do not propagate to a particular node in the network, and report the causes for such occurrences.

Parameters

-help	Prints out the command usage
-clock <i>clock_list</i>	List or collection of clocks that are to be reported.
-max_paths <i>number of paths</i>	Reports number of maximum clock paths per clock.
-to <i>pin_port_list</i>	Specifies the pin/port list.
-verbose	Generates a verbose report for clock propagation stop reason.
-view <i>viewName</i>	Generates a report for the specified analysis view.
> <i>filename[.gz]</i> >> <i>filename[.gz]</i>	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. Note: To write a compressed report, add the .gz extension to the file name.

Examples

- The following command reports the specified clocks and pin details:

```
tempus > report_clock_propagation -clock clk1 -to f0/QN
Clock: clk1
Point: f0/QN
View: view1
Reason 1: The clock 'clk1' propagation stops across the trigger arc:
(f0/CK->f0/QN)
The partial clock path:
```

Source	Sink	ArcType	ArcSense
clk1	f0/CK	(net)	(net)
f0/CK	f0/QN	rising_edge	non_unate

- The following command shows that clock propagation stops due to an inactive timing arc from b12/A to b12/Y:

```
set_disable_timing -from A -to Y b12
report_clock_propagation -to u99/CK -clock CLK_W_4
Clock: CLK_W_4
Point: u99/CK
Reason 1: The clock 'CLK_W_4' propagation stops due to the inactive timing arc:
(b12/A->b12/Y)
The partial clock path:
```

Source	Sink	ArcType	ArcSense
CLK4	b11/A	(net)	(net)
b11/A	b11/Y	combinational	positive_unate
b11/Y	b12/A	(net)	(net)
b12/A	b12/Y	combinational	positive_unate

- The following command shows that clock propagation stops due to no clock source found:

```
report_clock_propagation -to launchff/Q -clock [get_clocks gen_clk]
report_clock_propagation -to seg3/u15/Q -clock CLK_W_5_gen
Clock: CLK_W_5_gen
Point: seg3/u15/Q
```

Reason 1: The generated clock 'CLK_W_5_gen could not be created on its root pin 'seg3/u15/Q' because no clock source found for it

- The following command shows that clock propagation stops at the register clock pin as all the arcs from the clock pin of the register have been disabled:

```
set_disable_timing -from A -to Y seg3/u17_a
report_clock_propagation -to seg3/u14/CK -clock CLK_W_3
```

Clock: CLK_W_3

Point: seg3/u14/CK

Reason 1: The clock 'CLK_W_3' propagation stops due to the inactive timing arc:
(seg3/u17_a/A->seg3/u17_a/Y)

The partial clock path:

Source	Sink	ArcType	ArcSense
CLK3	seg3/u16/A	(net)	(net)
seg3/u16/A	seg3/u16/Y	combinational	positive_unate
seg3/u16/Y	seg3/u17/A	(net)	(net)
seg3/u17/A	seg3/u17/Y	combinational	positive_unate
seg3/u17/Y	seg3/u17_a/A	(net)	(net)
seg3/u17_a/A	seg3/u17_a/Y	combinational	positive_unate

Related Commands

- [set_disable_timing](#)

report_clock_sense

report_clock_sense

[-help]

Reports all clock sense settings in the design.

Parameters

-help	Prints out the command usage.

report_clock_timing

```
report_clock_timing
[-help]
[-cpr_relative]
[-latency_greater_than]
-type [skew | interclock_skew | jitter | summary | latency | cpr_stage_count
      [ [-launch | -capture]
        [-rise | -fall]
        | [-histogram [-histogram_range interval size]]
        [-logic_level [-source {clock_root | generated_clock}]]
      ]
    ]
[-absolute_compare]
[-early | -late]
[-clock clock_list]
[-from_clock from_clock_list]
[-to_clock to_clock_list]
[-from from_list]
[-to to_list]
[-nworst worst_entries]
[-greater_than lower_limit]
[-view view_name]
[-verbose]
[-format column_list]
[-tcl_list]
[ {> | >>} filename]
```

Generates a clock analysis report for the current design. The software generates a separate report for each specified clock or pair of clocks. You specify the clocks using the `-clock` parameter, and clock pairs using the `-from_clock` and `-to_clock` parameters. You can use the `-nworst` and `-greater_than` parameters with the `-from_clock` and `-to_clock` parameters to generate reports with skew to the specified sink pins. You can use the `-early` and `-late` parameters to specify the type of skew to be reported.

Note: To remove common path pessimism from the reported skew, use the [timing timing_analysis_cpr](#) both setting before using the `report_clock_timing` command. The report contains a separate column for common path adjustment values.

You can use the `report_clock_timing` command to perform MMMC based SSTA analysis. In MMMC mode, the command reports the latency and clock skew for all individual views. You can use the `report_clock_timing -view` parameter to report clock timing for a user-specified view.

Parameters

-help	Prints out the command usage.
{> >>} <i>filename</i>	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <i>filename</i> parameter must be the last argument in the list. The <i>filename</i> and -tcl_list parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the .gz extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
-absolute_compare	Reports skews with values compared in absolute form.
-clock <i>clock_list</i>	Specifies the list of clocks to be reported. The software generates a separate report for each clock that you specify in the <i>clock_list</i>. <i>Default:</i> Skew report is generated for all the clocks in a design.
-cpr_relative	Reports the latency in skew reports from the CPR common pin. When specified, the reports are printed with latency measured from branch point to the register's CK pin. The CPR value is no longer required in reports.
-early	Uses hold skew to generate the report. Hold skew is the difference between minimum latency at the start point flip-flop and the maximum latency at the end point flip-flop. <i>Default:</i> Uses the setup skew.

<code>-format column_list</code>	Specifies which columns to display for path reports, and the order in which they should appear. For example: <pre>-format {instance arc pin cell slew load}</pre> The <code>-format</code> parameter can be used only for latency or skew reports (<code>-type skew</code>, <code>-type interclock_skew</code>, or <code>-type latency</code>), and if the <code>-verbose</code> parameter is specified.
<code>-from from_list</code>	Specifies the list of sequential device clock pins or ports to consider as from-pins in the generated report. If any pin in the <code>from_list</code> is not a sequential device clock pin, it is replaced with all the sequential device clock pins in the transitive fanout of the named pin. If there are no sequential pins in the transitive fanout of the pin, the software drops the pin from the list and generates a warning message.
<code>-from_clock from_clock_list</code>	
	Specifies the list of from-clocks to be used in generating the current interclock skew report. You can use this option only in an interclock skew report. <i>Default:</i> Report is generated considering all clocks as from-clocks.
<code>-greater_than lower_limit</code>	Reports skews with values greater than the <code>lower_limit</code> value.

<code>-histogram</code>	Generates a textual histogram of the latency report. The <code>-histogram</code> parameter can be used only when <code>-type latency</code> is specified. When specified in conjunction with the <code>-clock</code> parameter, the software limits the latency reporting to the specified clocks only. When specified with the <code>-greater_than</code> parameter, the software limits the latency reporting to clocks with a latency value that is greater than the specified value. Note: The <code>-histogram</code> parameter cannot be specified in conjunction with the following parameters: <code>-launch</code>, <code>-capture</code>, <code>-from</code>, <code>-to</code>, <code>-from_clock</code>, <code>-to_clock</code>, <code>-verbose</code>, <code>-nworst</code>.
<code>-histogram_range interval_size</code>	Generates the histogram report at the specified intervals. The interval size specified must be a positive integer or decimal values. For example, if the maximum latency value is 437, and you specify <code>-histogram_range 50</code>, the histogram would be generated with intervals of: 0-50, 50-100, 100-150, ... 400-450. Note: The unit of <code>interval_size</code> will be the same as that used for generating the timing report. This parameter can be used only when the <code>-histogram</code> parameter is specified.
<code>-late</code>	Uses setup skew to generate the report. Setup skew is the difference between the maximum latency at the start point flip-flop and minimum latency at the end point flip-flop.
<code>-latency_greater_than lower_limit</code>	Reports are filtered based on the specified <code>-type</code> option. When specified with: • <code>-type skew</code> or <code>interclock_skew</code>: Reports are filtered for latency greater than the provided value or depth. • <code>-type cprpr_stage_count</code>: Reports are filtered for depth greater than the provided value.

<code>-launch -capture</code>	When specified with <code>-type latency</code>, generates a report of either the launch latency values (<code>-launch</code>), or the capture latency values (<code>-capture</code>). Note: You can specify these parameters only with <code>-type latency</code>. <i>Default:</i> <code>-launch</code>
<code>-logic_level</code>	Reports the levels (the stage count of gates) between the clock root, or generated clock root, and the capturing register. The <code>-logic_level</code> parameter can be used only when <code>-type latency</code> is specified. The <code>-logic_level</code> parameter cannot be specified in conjunction with the following parameters: <code>-launch</code>, <code>-capture</code>, <code>-from</code>, <code>-to</code>, <code>-from_clock</code>, <code>-to_clock</code>, <code>-verbose</code>, <code>-nworst</code>.
<code>-nworst worst_entries</code>	Specifies the number of entries to be reported per clock domain. <i>Default:</i> 1
<code>-rise -fall</code>	Specifies active transition at sequential devices clock pins. The <code>-rise</code> and <code>-fall</code> parameters are mutually exclusive and cannot be specified together. Note: You can specify these parameters only with the <code>-type latency</code> parameter.
<code>-source {clock_root generated_clock}</code>	Reports the latency from either the master clock, or the generated clock that was derived from it. The <code>-source</code> parameter can be used only when <code>-logic_level</code> is specified. The <code>-source</code> parameter cannot be specified in conjunction with the following parameters: <code>-launch</code>, <code>-capture</code>, <code>-from</code>, <code>-to</code>, <code>-from_clock</code>, <code>-to_clock</code>, <code>-verbose</code>, <code>-nworst</code>. <i>Default:</i> Reports the latency from the master clock (<code>-source clock_root</code>)

<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-to to_list</code>	Specifies the list or collection of sequential device clock pins or ports to be considered for reporting. If any pin in the <code>to_list</code> is not a sequential device clock pin, it is replaced with all the sequential device clock pins in the transitive fanout of the named pin. If there are no sequential pins in the transitive fanout of the pin, the software drops the pin from the list and generates a warning message.
<code>-to_clock to_clock_list</code>	Specifies the list of to-clocks to be used in generating the current interclock skew report. You can use this option only in an interclock skew report. <i>Default:</i> Report is generated considering all clocks as to-clocks.
<code>-type {skew interclock_skew jitter summary latency cppr_stage_count}</code>	Specifies the type of report to generate. The <code>-type</code> options are described below: • <code>skew</code>: Reports the skew for all clocks, or for clocks that you specify using the <code>-clock</code> parameter. • <code>interclock_skew</code>: Reports the skew between all clocks (excluding same clock pair) in the design, or between clocks that you specify using the <code>-from_clock</code> and <code>-to_clock</code> parameters. Note: The <code>skew</code> option can be used to report the previous results that show the missed out same clock skew values (reported using the <code>interclock_skew</code> option). • <code>jitter</code>: Reports the difference in late and early arrival times of a clock phase at a clock end point. When specified, the software generates a clock jitter report for one clock end point, for each clock in the design.

You can generate a jitter report for all clocks, or clocks specified with the `-clock` parameter. You can limit the report to a specific clock end point, using the `-to` parameter.

Note: The `report_clock_timing -type jitter` option can be used only when the software is in On-Chip Variation (OCV) timing analysis mode. Jitter analysis does not remove any common path pessimism.

- `summary`: Generates a summary report for each analyzed clock that includes the following information:
 - When setup skew is used (`-late`):
 - maximum launch latency
 - minimum capture latency
 - maximum setup skew
 - When hold skew is used (`-early`):
 - minimum launch latency
 - maximum capture latency
 - maximum hold skew
- `latency`: Reports the network and source latency values for all the clock pins in the design, or for clock pins that you specify using the `-clock` parameter.
- `cprr_stage_count`: The generated report is arranged in terms of difference of stages from common pin to CK pin. The reports are generated on the basis of logical CPPR points derived between each pair of phases reaching the launch/capture CK pins. Only same clock pairs (similar to type skew) are picked. For example,

```
Branch Point Difference Depth Clock Pin
```

```
-----  
inv2/Y  
5 r ffc1/CK
```

<code>-verbose</code>	4 1 f ffc3/CKN Generates a report that contains the full clock path from the clock source to the sink pin (the clock pin of the flop or latch). You can specify the <code>-verbose</code> parameter only for skew or latency reports (<code>-type skew</code>, <code>-type interclock_skew</code>, or <code>-type latency</code>). When this parameter is specified in SOCV mode, the intermediate arrival times of pins are shown as "-" in the report output.
<code>-view view_name</code>	Generates a report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

- The following command reports skew details for the specified list of clocks:

```
tempus > report_clock_timing -clock clk1 -type skew
Clock: clk1
Analysis View: view1
```

Skew	Latency	CPPR	Clock Pin	
	0.000		r	f0/CK
0.000	0.000	-0.000	r	f1/CK

- The following command uses hold skew to generate a report and shows details of skew between all the clocks:

```
tempus > report_clock_timing -early -type interclock_skew
Clock: clk2
Analysis View: view1
```

Skew	Latency	CPPR	Clock Pin	
	0.000		r	f0/CK
-0.000	0.000	0.000	r	f1/CK

- The following command reports details of skew between all the clocks for the specified sequential device clock pins:

```
tempus > report_clock_timing -from_clock {refclk m_spi_clk} -type interclock_skew
Clocks: m_spi_clk -> m_clk
Analysis View: func_slow_RCMAX
```

Skew	Latency	CPPR	Clock Pin

	0.580		TST_INST/p88/ZN
			r SPI_INST/spi_sr_reg[7]/CK
			TST_INST/p97/Z
-3.761	4.340	0.000	r TDSP_INST/as_reg/CK

- The following command uses hold skew (greater than 2) to generate a report and shows details of skew between all the clocks:

```
tempus > report_clock_timing -from {refclk m_spi_clk } -type skew -greater_than 2
```

Clock: m_clk

Analysis View: scan_fast_RCMIN

Skew	Latency	CPPR	Clock Pin

	3.960		r TDSP_INST/areg[0]/CK
2.735	1.225	-0.000	r ROM_512x16_INST/CLK

Clock: m_clk

Analysis View: scan_slow_RCMIN

Skew	Latency	CPPR	Clock Pin

	3.960		r TDSP_INST/areg[0]/CK
2.735	1.225	-0.000	r ROM_512x16_INST/CLK

- The following command generates the histogram latency report at the specified interval range:

```
tempus > report_clock_timing -clock m_clk -histogram -type latency -histogram_range 50  
[Delay Chart: TST_INST/p21/Z(m_clk)]
```

```
-----  
Min Delay :      1.118  
Max Delay :      4.332  
Count : 406  
-----
```

Delay Range					
Min	Max	Count	1	10	100

0.000	50.000	406	oooooooo		oooo
[Delay Chart: TST_INST/p21/Z(m_clk)]					

```
-----  
Min Delay :      1.052  
Max Delay :      3.995  
Count : 406  
-----  
-----
```

Delay Range					
Min	Max	Count	1	10	100
0.000	50.000	406	oooooooo		oooo

- The following command uses setup skew to generate the report and shows skew details for the specified list of clocks:

```
tempus > report_clock_timing -clock m_clk -late -type skew
Clock: m_clk
Analysis View: scan_fast_RCMIN
```

Skew	Latency	CPPR	Clock Pin	
	3.960		r	TDSP_INST/acc_reg[0]/CK
2.735	1.225	-0.000	r	ROM_512x16_0_INST/CLK

```
Clock: m_clk
Analysis View: scan_slow_RCMIN
```

Skew	Latency	CPPR	Clock Pin	
	3.960		r	TDSP_INST/acc_reg[0]/CK
2.735	1.225	-0.000	r	ROM_512x16_0_INST/CLK

- The following command reports hold skew details for the specified list of clocks:

```
tempus > report_clock_timing -clock m_clk -early -type skew
Clock: m_clk
Analysis View: scan_fast_RCMIN
```

Skew	Latency	CPPR	Clock Pin	
	1.225		r	ROM_512x16_0_INST/CLK
2.765	3.990	0.000	r	TSP_CRE/PRG_BS/dt_reg[12]/CK

```
Clock: m_clk
Analysis View: scan_slow_RCMIN
```

Skew	Latency	CPPR	Clock Pin	
	1.225		r	ROM_512x16_0_INST/CLK
2.765	3.990	0.000	r	TSP_CRE/PRG_BS/dt_reg[12]/CK

- The following command reports launch latency values for the specified list of clocks:

```
tempus > report_clock_timing -clock m_clk -capture -type latency
Clock: m_clk
Analysis View: func_slow_RCMAX
```

```
---Latency---
```

Source	Network	Total	Clock Pin	
0.000	1.102	1.102	r	ROM_512x16_0_INST/CLK

Clock: m_clk

Analysis View: func_fast_RCMAX

---Latency---

Source	Network	Total	Clock Pin	
0.000	1.310	1.310	r	ROM_512x16_0_INST/CLK

- The following command reports latency details for the specified number of entries per clock domain:

```
tempus > report_clock_timing -clock m_clk -nworst 4 -type latency
```

Clock: m_clk

Analysis View: func_slow_RCMAX

---Latency---

Source	Network	Total	Clock Pin	
0.000	4.735	4.735	r	DM_IST/write_reg/CK
0.000	4.735	4.735	r	DM_IST/top_flg_reg/CK
0.000	4.735	4.735	r	DM_IST/read_reg/CK
0.000	4.735	4.735	r	DM_IST/state_reg[3]/CK

- The following command reports latency details for all the levels between the generated clock root, and the capturing register.

```
tempus > report_clock_timing -source generated_clock -logic_level -type latency
```

Start point:refclk(refclk)

Delay	Count	End Point
3.697	3	SPI/spr_108/CK r
3.697	3	SPI/spr_107/CK r
3.697	3	SPI/spr_105/CK r
3.697	3	SPI/spr_103/CK r
3.697	3	SPI/spr_101/CK r
3.697	3	SPI/spr_100/CK r
3.697	3	SPI/spr_104/CK r
3.697	3	SPI/spr_102/CK r
3.697	3	SPI/spr_106/CK r
3.697	3	SPI/spr_109/CK r
3.697	3	SPI/spr_110/CK r

- The following command reports worst case skew for all the clocks in a design:

```
tempus > report_clock_timing -type skew -nworst 4
```

Clock: CLK_W_4

Skew	Latency	Clock Pin

	0.150 r	u99/CK
0.000	0.150 r	u55/CK

Clock: CLK_W_3

Skew	Latency	Clock Pin

	0.682 r	seg3/u9/CK
0.061	0.621 r	seg3/u14/CK

Clock: CLK_W_2

Skew	Latency	Clock Pin

	0.682 r	seg2/u9/CK
0.061	0.621 r	seg2/u14/CK

Clock: CLK_W_1

Skew	Latency	Clock Pin

	0.682 r	seg1/u9/CK
0.061	0.621 r	seg1/u14/CK

Here 'r' indicates the transition (r - rise, f - fall) at the reported register clock pin.

- The following command reports interclock skew with -from_clock, -to_clock, -from, and -to parameters defined:

```
tempus > report_clock_timing -type interclock_skew -nworst 10 -from CLK4 -to u5/CK -
from_clock CLK_W_4 -to_clock CLK_W_4_gen2
```

Clocks: CLK_W_4 -> CLK_W_4_gen2

Skew	Latency	Clock Pin

		CLK4
	0.180 r	u99/CK
		u2/Q
		u8/Q
-0.205	0.386 ri	u5/CK

Here 'r' indicates the transition (r - rise, f - fall) at the reported register clock pin. The 'i' refers to the 'inverted' polarity of the clock signal at the reported register clock pin.

- The following command reports skew for all clocks in the design including common path pessimism removal:

```
tempus > set_db timing_analysis_cpvr both
tempus > report_clock_timing -type skew -nworst 10
```

```
Clock: CLK_W_4
Skew      Latency      CPPR      Clock Pin

report_clocks

```
report_clocks
[-description]
[-arrival_points]
[-phase_shift_table]
[-total_shift_table]
[-uncertainty_table]
[-adjustment_table]
[-delay_adjustment_table]
[-source_insertion]
[-insertion]
[-hierarchy]
[-groups]
[-clocks clk_signame | clk_signame_list]
[-view view_name]
[{> | >>} filename | -tcl_list]
```

Reports information on clocks created with the [create_clock](#) and [create_generated_clock](#) command. The report includes information about all clock waveforms, clock arrival points, and clock uncertainties.

Use the `-description`, `-arrival_points`, `-uncertainty_table`, and the `*_table` parameters to specify different parts of the report. If one of these options is supplied, only the section that the option corresponds to is reported. If other options are supplied, those sections are also reported.

Based on the current setup or hold analysis mode, the following parameters report only one of the late or early tables:

- `-phase_shift_table`
- `-total_shift_table`
- `-uncertainty_table`
- `-adjustment_table`
- `-delay_adjustment_table`

However, in simultaneous (setup and hold) mode both the tables are reported.

✓ The `report_clocks` command only reports constraints with respect to clock waveforms. Use the `report_ports -type` command for constraints applied to clock pins.

Parameters

<pre>{> >>} filename</pre>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <code>filename</code> parameter must be the last argument in the list. The <code>filename</code> and <code>-tcl_list</code> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
<pre>-adjustment_table</pre>	Reports two tables that detail the hold and setup cycle adjustments between clock waveforms as set by the <code>set_multicycle_path</code> command. Note: If specific ideal (or generated) clocks are requested with the <code>-clocks clock_name_list</code> option, then only the relationships between those clock signals are reported.
<pre>-arrival_points</pre>	Reports only the clock arrival points. A clock arrival point is the pin where the <code>create_clock</code> or <code>create_generated_clock</code> command has been asserted. Note: This parameter is obsolete and will be removed in a future release.
<pre>-clocks clk_signame clk_signame_list</pre>	Requests information on a specific ideal (or generated) clock. If a list is given, only information about those clocks is reported. You can use wildcards in the names. <i>Default:</i> All clocks, except generated clocks, are reported. Use the <code>-generated</code> option to report generated clocks. Note: This parameter is obsolete and will be removed in a future release. Cadence recommends that you specify clock names without the <code>-clocks</code> parameter.

<code>-delay_adjustment_table</code>	Reports two tables that detail the early and late path delay adjustments between clock waveforms as set by the <code>set_max_delay</code> and <code>set_min_delay</code> commands. Note: If specific ideal (or generated) clocks are requested with the <code>-clocks clock_name_list</code> option, then only the relationships between those clock signals are reported.
<code>-description</code>	Reports only the description of the specified clock waveform(s).
<code>-generated</code>	Includes information on generated clocks in the report, such as source and master clock of the generated clock, and other information specified in the <code>create_generated_clock</code> constraints. The report uses the internal clock names created by the system, if you did not specify new clock names while creating these clocks. Note: This parameter is obsolete and will be removed in a future release. The software now reports generated clocks by default.
<code>-groups</code>	Reports the existing clock groups.
<code>-hierarchy</code>	Reports the inter-clock relationship in tree style format.
<code>-insertion</code>	Reports the network insertion delays specified on clock waveforms. The values in the table are in <code>min:typ:max</code> format.
<code>-phase_shift_table</code>	Reports the table that details the phase shift between clock waveforms. Based upon the current analysis mode, the table shows the phase shifts either in late or early mode. In case of simultaneous setup hold mode, both the tables are reported for phase shift in late and early mode. Note: If specific ideal (or generated) clocks are requested with the <code>-clocks clock_name_list</code> option, then only the relationships between those clock signals are reported.
<code>-source_insertion</code>	Reports the source insertion delays specified on clock waveforms.

<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-total_shift_table</code>	Based on the current analysis mode, reports (late or early mode) details and the relationship between clock waveforms. In case of simultaneous setup hold mode all the details are reported. Note: If specific ideal (or generated) clocks are requested with the <code>-clocks clock_name_list</code> option, then only the relationships between those clock signals are reported.
<code>-uncertainty_table</code>	Based on the current analysis mode, reports one of the tables (late mode or early mode) that detail the uncertainty between clock waveforms as specified using the <code>set_clock_uncertainty</code> command. In case of simultaneous setup hold mode both the tables are reported. The tables report only those clock waveforms for which uncertainty has been defined using the <code>set_clock_uncertainty</code> command. Note: If specific ideal (or generated) clocks are requested with the <code>-clocks clock_name_list</code> option, then only the relationships between those clock signals are reported.
<code>-view view_name</code>	Generates a clock report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

- The following command reports the clock arrival points, and details of the clock waveform(s):

```
tempus > report_clocks -arrival_points -description
```

```
-----
```

- The following command reports uncertainty information as per the defined assertions:

```
tempus > set_clock_uncertainty 5 CLK_W_1
tempus > set_clock_uncertainty 4 -from CLK_W_1 -to CLK_W_4_gen1
tempus > set_clock_uncertainty 6 -from CLK_W_2 -to CLK_W_4_gen2
tempus > report_clocks -uncertainty_table
```

Clock To Clock Uncertainty (Late)

From	To	L->L	L->T	T->L	T->T
*	CLK_W_1	5.000	5.000	5.000	5.000
CLK_W_1	CLK_W_4_gen1	4.000	4.000	4.000	4.000
CLK_W_2	CLK_W_4_gen2	6.000	6.000	6.000	6.000

Clock To Clock Uncertainty (Early)

From	To	L->L	L->T	T->L	T->T

*	CLK_W_1	-5.000	-5.000	-5.000	-5.000
CLK_W_1	CLK_W_4_gen1	-4.000	-4.000	-4.000	-4.000
CLK_W_2	CLK_W_4_gen2	-6.000	-6.000	-6.000	-6.000

- The following command reports the phase shift between clock waveforms for the defined clock:

```
tempus > create_clock -name "CLK_W_1" -add -period 60 -waveform {0 30}
tempus > report_clocks CLK_W_1 -phase_shift_table
```

Clock To Clock Phase Shift (Late)					

From	To	L->L	L->T	T->L	T->T

CLK_W_1	CLK_W_1	60.000	0.000	60.000	60.000

Clock To Clock Phase Shift (Early)

From	To	L->L	L->T	T->L	T->T

CLK_W_1	CLK_W_1	0.000	-60.000	0.000	0.000

- You can use the following command to define uncertainty for a clock:
Based on the current analysis mode, reports (late or early mode) details and the relationship between clock waveforms.

```
tempus > set_clock_uncertainty 2 CLK_W_1
```

The following command reports (late or early mode) details and displays the changed shift values:

```
tempus > report_clocks -total_shift_table CLK_W_1
```

Total Clock To Clock Phase Shift Required (Late)					

From	To	L->L	L->T	T->L	T->T

CLK_W_1	CLK_W_1	58.000	-2.000	58.000	58.000

Total Clock To Clock Phase Shift Required (Early)					

```
-----
From      To      L->L  L->T  T->L  T->T
-----
CLK_W_1 CLK_W_1 2.000 -58.000 2.000 2.000
-----
```

You can see that the uncertainty is subtracted from the phase shift.
Consider the following example path:

```
Path 1: MET Setup Check with Pin u2/CK
Endpoint: u2/D (v) checked with leading edge of 'CLK_W_1'
Beginpoint: CLK2 (v) triggered by trailing edge of 'CLK_W_2'
Path Groups: {CLK_W_1}
Other End Arrival Time 0.000
- Setup 0.188
+ Phase Shift 15.000
- Uncertainty 2.000
= Required Time 12.812
- Arrival Time 12.463
= Slack Time 0.349
Clock Fall Edge 12.500
= Beginpoint Arrival Time 12.500
-----
```

Load	Slew	Delay	Arrival Time	Cell	Arc	Pin
0.034	0.003	12.500			CLK2 v	CLK2
0.003	0.003	-0.037	12.463	BUF	A v -> Y v	u10999/Y
0.003	0.003	0.000	12.463	DFF	D v	u2/D

Here the begin point CLK_W_2 to end point CLK_W_1 shows a phase shift value of 15.00. This means that if a path starts from the falling edge of CLK_W_2 , and ends at the rising edge of CLK_W_1, the phase shift is 15.00. In other words, when the timing (setup time) is reported, the required time at the end point begins with 15.00 (in addition to adjustments like setup time, time borrowing, uncertainty, etc). However, the arrival time of this path starts at 12.500.

- When the software is in multi-mode multi-corner timing analysis mode, the software reports the clock information for each active analysis view:

```
tempus > report_clocks -total_shift_table -description
```

```
-----
Clock Descriptions
-----
```

```
Attributes
-----
```

Clock Name	Source	View	Period	Lead	Trail	Generated	Propagated

```

Reports constraint information of current design. The constraints information includes information such as whether or not constraint is violated, by how much amount, and the worst violator object.

The following timing checks are reported when you use the `report_constraint` command:

- All setup and hold checks
- DRV
- Clock and asynchronous checks including `pulse_width`, `min_period`, `recovery`, `removal`, `clock_gating_setup`, `clock_gating_hold`, `skew`

You can specify the design rule constraints on pins, ports, cells, or a design using the commands: `set_min_fanout`, `set_max_fanout`, `set_min_transition`, `set_max_transition`, `set_min_capacitance`, and `set_max_capacitance`.

The `report_constraint` command checks against the worst design rule constraint between the library constraint limit and the user-specified constraint value, when both are applied on the violating pin or port.

The `report_constraint` command supports multi-threaded reporting. You can make the following

settings to enable multi-threaded reporting:

```
set_multi_cpu_usage -localCpu number_of_CPU  
set_table_style -no_frame_fix_width [-nosplit]
```

By default, the `report_constraint` command reports only the mean slews in transition DRV checks. You can enable DRV checking to use mean as well as the n-sigma slew values (in SOCV mode), with the following setting:

```
set timing_report_max_transition_check_using_nsigma_slew true
```

Configurable DRV Reports

Tempus allows you to perform design rule violation (DRV) checks to ensure that the netlist meets the design rule constraints specified in the design library. To enable configurable DRV reporting, you can use the `timing_report_constraint_format` attribute. For example,

```
set timing_report_constraint_format {list of DRV fields}  
report_constraint -drv_violation_type {list of DRV checks} \  
    -all_violators | pin_or_port_list
```

You can also use the following command to specify DRV fields:

```
report_constraint -drv_violation_type {list of DRV checks} -drv_fields field_list
```

The field list specified with the `-drv_fields` parameter has higher precedence and will override the field list specified with the `timing_report_constraint_format` global variable. If DRV fields are not specified with this global variable (or with the `report_constraint -drv_fields` command), then the default set of DRV fields will be displayed. For a complete list of DRV fields, refer to the [DRV Fields](#) table.

For more information, refer to the [Design Rule Violation \(DRV\) Reporting](#) section in the *Tempus Stylus User Guide*.

Parameters

<code>{> >>} filename</code>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <code>filename</code> parameter must be the last argument in the list. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. Default: Report is displayed on standard output without being saved.
---	--

<code>-all_violators</code>	Reports the worst negative slack per violating pin against all the timing and design rule constraint checks. For timing checks, the violations are reported at timing endpoints. The DRV is checked and reported on leaf pins and ports. The supported check types are: • setup • hold • clock_gating_setup • clock_gating_hold • recovery • removal • clock_period • pulse_width • max_capacitance • max_transition • max_fanout • min_capacitance • min_transition • min_fanout • skew • pulse_clock_max_width • pulse_clock_min_width • pulse_clock_max_transition • pulse_clock_min_transition You can use the <code>-all_violators</code> parameter for reporting specific check types to generate report for that particular check type only. For example, you can use <code>-all_violators</code> with <code>-late</code> to report setup checks and path delays from <code>set_max_delay</code>.
<code>-check_type</code>	Reports setup or hold checks. The supported check types are: • <code>clock_gating_setup</code>: Reports only the paths that end at the <code>clock_gating_setup</code> timing check. • <code>clock_gating_hold</code>: Reports only the paths that end at the

clock_gating_hold timing check.

- **electromigration:** Reports signal EM analysis related violations. When high density current passes through a thin metal wire, the high energy electrons exert forces on atoms causing them to migrate. Electromigration (EM) can drastically reduce the lifetime of a chip by increasing the resistivity of a metal wire or creating a short circuit between adjacent lines. When this option is specified, the software reports standard cell level electromigration violations.
- **recovery:** Reports paths that end at the recovery timing check.
- **removal:** Reports paths that end at the removal timing check.

Note: The check types - recovery, removal, clock_gating_setup, and clock_gating_hold are also supported in AOCV mode.

- **pulse_width:** Reports only the paths that end at the pulse_width timing check.

If you do not specify the `-all_violators` parameter, then the pulse_width option reports only one entry of the most critical pulse_width check. The DRV checks also report only the most critical entry.

To report all the violated pulse_width checks, you need to specify `report_constraint -check_type pulse_width -all_violators` command (which is consistent with other check types of the `report_constraint` command).

To report both violating and met entries, you can use the `report_min_pulse_width` command.

- **clock_period:** Reports only the paths that end at the clock_period timing check.
- **skew:** Reports skew checks.

The `report_constraint` command performs skew checks by default.

Skew checks are implemented as setup checks that are reported in the late analysis or simultaneous mode. These checks are not reported in the early mode. Skew checks are performed assuming the signal and reference clocks have the same frequency. If the frequencies of the signal and reference clocks are different, a warning message is displayed.

- **pulse_clock_max_width:** Reports the maximum pulse clock width checks set using the set using `set_pulse_clock_max_width` command.

	• <code>pulse_clock_min_width</code>: Reports the minimum pulse clock width checks. • <code>rail_swing</code>: Reports details related to the rail swing checks. For rail swing check settings, you can use the following attributes: ◦ <code>timing_rail_swing_checks_low_voltage_threshold</code> ◦ <code>timing_rail_swing_checks_high_voltage_threshold</code>
<code>-clock</code>	Specifies that the DRV checks will be restricted to the clock network. If any pin is part of both the clock and data network, it will be reported as a clock.
<code>-connection_class</code>	Reports violations if the connection class attributes of the driving pin and receiving pin of a net are different.
<code>-data</code>	Specifies that the DRV check will be restricted to the data network. If any pin is part of both the clock and data network, it will be reported as a clock network pin. By default, the DRV checks are applied to both clock and data networks.
<code>-drv_abs_margin</code> <i>float</i>	Specifies the absolute DRV margin value applied to obtain the threshold transition.
<code>-drv_fields</code> { <i>field_list</i> }	Allows only the specified fields to be included in the DRV report - in the same order as defined. For a complete list of DRV fields, refer to the DRV Fields table.
<code>-drv_output_format</code> { <i>txt</i> <i>csv</i> }	Specifies the DRV output format – txt or CSV. The default value is “txt”.
<code>-drv_ratio_margin</code> <i>float</i>	Specifies the ratio of the DRV margin value applied to obtain the threshold transition.

-
drv_violation_type

Reports DRV violations. The supported DRV check types are:

- **max_capacitance:** Reports pins having the worst `max_capacitance` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual capacitance is greater than the `max_capacitance` value specified in library and timing constraints file.
 - **min_capacitance:** Reports pins having the worst `min_capacitance` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual capacitance is less than the `min_capacitance` value specified in the library and timing constraints file.
 - **max_transition:** Reports pins having the worst `max_transition` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual transition is greater than the `max_transition` value specified in the library and timing constraint file.
- Note:** These checks are not reported in hold analysis mode. The `set_si_mode -enable_drv_with_delta_slew true` setting is required for `max_transition` DRV violations with SI slew.
- **min_transition:** Reports pins having the worst `min_transition` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual transition is less than the `min_transition` value specified in the library and timing constraints file.
 - **max_fanout:** Reports pins having the worst `max_fanout` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual fanout is greater than the `max_fanout` value specified in the library and timing constraints file.
 - **min_fanout:** Reports pins having the worst `min_fanout` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual fanout is less than the `min_fanout` value specified in the library and timing constraints file.
 - **pulse_clock_max_transition:** Reports maximum pulse clock transition checks.
 - **pulse_clock_min_transition:** Reports minimum pulse clock transition checks.

<code>-early</code>	Reports all of the hold checks, including regular, clock_gating_hold, and data-to-data hold checks. Also reports path delays from set_min_delay. Note: This parameter does not report removal checks.
<code>-em_type {peak rms avg all}</code>	Reports DRV violations as per the specified EM type table lookup. When this parameter is specified, the software reads the em_max_toggle_rate table in the Liberty library for the specified EM current type (RMS, peak, or average).
<code>-late</code>	Reports all of the setup checks, including regular, clock_gating_setup, and data-to-data setup checks. Also reports path delays from set_max_delay. Note: This parameter does not report recovery checks.
<code>-max_pins_per_drv</code>	Reports the specified number of top worst violations per DRV category, such as, max_transition, max_capacitance. If this parameter is not specified, then by default 1000 entries per DRV category will be reported.
<code>pin_port_list</code>	Controls the output of DRV constraints. When specified, all DRV violations are reported for the specified pins or ports only.
<code>-retime {aocv path_slew_propagation aocv_path_slew_propagation}</code>	
	Reanalyzes the specified set of paths using the specified method. Note: The parameter supports setup/hold check types only. aocv: Re-evaluates the given set of graph-based analysis (GBA) paths by reverting back graph-based AOCV derate factors and applying path-based AOCV derates instead of less pessimistic derates. In this case the slew (and respective delays) values are worst that are propagated during graph-based analysis. aocv_path_slew_propagation: Re-evaluates the given set of graph-based analysis (GBA) paths by using path-based AOCV derates and delays using actual path-based propagated slew. path_slew_propagation: Re-evaluates the given set of graph-based analysis (GBA) paths by recalculating the delay values based upon actual propagated slew across the path. In this case the AOCV derates are the ones that are reported during graph-based analysis.

<pre>-retime_mode {path exhaustive}</pre>	Allows the <code>report_constraint</code> command to be run in exhaustive path-based analysis (PBA) mode. In this mode, the software will exhaustively examine <code>n</code> worst paths of the selected endpoints and then select the true worst path to be reported - based on retimed slacks of all the examined paths. To enable exhaustive mode, the use model is given below: <pre>report_constraint -all_violators -retime path_slew_propagation - retime_mode exhaustive</pre> When you use this parameter, reporting can be run time intensive as the software needs to do an exhaustive search for true worst paths. Therefore, it is recommended to use this option in the later phases of sign-off stage when there are very few violations left for analysis. <i>Default:</i> <code>path</code>
<pre>-verbose</pre>	Generates a report that displays the full data path with the accompanying required time and slack calculation.
<pre>-view viewName</pre>	Generates a report containing endpoint and other constraint information for the specified analysis view. You can only specify this parameter when the software is in multi-mode multi-corner analysis mode. <i>Default:</i> Generates a report containing the worst endpoint and constraint information based on all of the analysis views.
<pre>- worst_drv_per_net</pre>	Reports only the worst DRV violation per net.

DRV Fields

Field Name	Report Column	Description
capacitance_actual	Actual Capacitance	Specifies the actual minimum or maximum capacitance pin or port. This field is used to determine the capacitance slack value.
capacitance_slack	Capacitance Slack	Specifies the max_cap/min_cap slack at a pin or port.

direction	Direction	Specifies the pin or port direction.
driver_max_capacitance	Driver Required Maximum Capacitance	Specifies the max_capacitance limit at the driver pin or port.
driver_max_fanout	Driver Required Maximum Fanout	Specifies the worst max_fanout limit on the driver pin or port.
driver_max_transition	Driver Required Maximum Transition	Specifies the max_transition limit at the driver pin or port.
driver_min_capacitance	Driver Required Minimum Capacitance	Specifies the min_capacitance limit at the driver pin or port.
driver_min_transition	Driver Required Minimum Transition	Specifies the min_transition limit at the driver pin or port.
driver_pin	Driver	Specifies the leaf driver pin or port name.
driver_ref_cell	Driver Libcell	Specifies the leaf driver reference cell or port.
driver_transition	Driver Actual Transition	Specifies the actual transition at driver pin or port.
drv_source	Source of DRV	Specifies the source of the DRV constraint which is used for the DRV check. Reports 'library_constraint' or 'user_constraint' depending on which DRV violation checker is used.
edge	Edge	The signal transition direction on the net. Returns "rise" or "fall" if the DRV report corresponds to a rising or falling transition on the net.
fanout_actual	Actual Fanout	Specifies the actual minimum or maximum fanout at a pin or port. This field is used to determine the fanout slack value.
fanout_slack	Fanout Slack	Specifies the max_fanout/min_fanout slack at a pin or port.
hnet	Hierarchical Nets	Reports the hierarchical nets associated with violating constraints.
lib_constraint	Library Constraint	Specifies the value of the library constraint on the violating pin. If not defined, reports as "NA".

max_capacitance	Required Capacitance	Specifies the maximum capacitance limit for a pin.
max_clock_frequency	Frequency	Specifies the frequency of the clock reported under the max_frequency_clock field.
max_fanout	Required Fanout	Specifies the maximum fanout limit for a pin.
max_frequency_clock	Maximum Frequency Clock	Specifies the name of the highest frequency clock constraining the pin. For clock network pins, the fastest clock reaching the pin will be reported. For data network pins, the fastest launch clock reaching the pin will be reported.
max_slack	Worst Setup Slack	Specifies the worst setup slack through at a pin or port.
max_transition	Required Transition	Specifies the maximum transition limit for a pin or port.
min_capacitance	Required Capacitance	Specifies the minimum capacitance limit for a pin.
min_fanout	Required Fanout	Specifies the minimum fanout limit for a pin.
min_slack	Worst Hold Slack	Specifies the worst hold slack through at a pin or port.
min_transition	Required Transition	Specifies the minimum transition limit for a pin or port.
net	Net	Specifies the top flat net connected to violating pin (net name at topmost hierarchy) flat net.
hnet	Hierarchical Nets	Reports hierarchical nets. When the <code>timing_enable_hierarchical_get_nets_support</code> attribute set to <code>true</code> , the software enables support for displaying hierarchical net names.
net_fanout	Net Fanout	Specifies the number of leaf level load pins of the net connected to a pin or port.
net_resistance	NetResistance	Resistance of the net connected to a pin or port.

net_type	Net Type	Specifies one or more of the following identifiers to indicate a special net: • ideal: the net is marked ideal using the set_ideal_network command • clock: the net is part of a clock network • constant: the net is tied to logic 1/0 respectively • multidriven: the net has multiple driver • dont_touch: the net is marked as dont_touch using set_dont_touch command • "-": None of the above
partition	Partition	Specifies the name of the SPEF hierarchy the violating appears in.
pin	Pin	Reports the pin or port on which DRV check is performed
pin_type	Type	Specifies whether the pin/port is a data or a clock pin/port. Any clock network pin will be reported as CLOCK. Any that belongs to only data network will be reported as D. If a pin/port belongs to both data and clock networks, it will be reported as CLOCK.
receiver_max_transition	Receiver Required Maximum Transition	Specifies the max_transition limit at a receiver pin or port.
receiver_pin	Receiver	Specifies the leaf receiver pin name.
receiver_ref_cell	Receiver Libcell	Specifies the leaf reference cell name of a receiver pin.
receiver_transition	Receiver Actual Transition	Specifies the actual transition at a receiver pin or port.
ref_cell	Violating Libcell	Specifies the reference library cell the violating pin is attached to.
sequential	Sequential	Specifies if the pin belongs to a sequential cell or a combinational cell. For ports, the report will show "false".
total_capacitance	TotalCapacitance	Total capacitance of the net connected to a pin or port.

transition_actual	Actual Transition	Specifies the actual minimum/maximum transition at a port. This can be base transition or base plus crosstalk induced transition depending on the timing_max_transition_use_si_transition setting to false (default) or true, respectively.
transition_si	SI Transition	Specifies only the delta SI transition time at a pin or port. The total transition time comprises of the base transition time (transition value without SI crosstalk analysis) as well as delta SI transition time.
transition_sigma	Transition N-Sigma	Specifies the N-Sigma multiplier defined for transition value in the <code>set_socv_reporting_nsigma_multiplier -transition_sigma <nsigma></code> command. This field will be reported for SOCV STA, under the <code>timing_report_max_transition_check_using_nsigma_setting true</code> setting. This is sensitive to views and -data and -clock specific. Note: This field will impact transition_actual and transition_slack computation for max_transition, min_transition, pulse_clock_max_transition, and pulse_clock_min_transition checks.
transition_slack	Transition Slack	Specifies the max_transition/min_transition slack at a pin/port pin/port.
user_constraint	User Constraint	Specifies user defined tran/cap/fanout limit value set by constraints as command or through SDC on the violating pin. If not defined, reports as "NA".
view	View	Name of the pertaining analysis view.

Examples

- The following command reports the worst negative slack per violating pin under pulse width checks:

```
tempus > report_constraint FE_C9/A -all_violators -check_type pulse_width

# format : frame 0 : split 0
**WARN: (TCLCMD-1470): Pins/ports are only supported with '-drv_violation_type'
option

Check type : pulse_width
```

SEQUENTIAL CLOCK PULSE WIDTH

Pin	Required	Actual Pulse	Slack	View Name
	Pulse Width	Width		

RM_25_TS_INST/RM_25_INST/CLK (high)	0.061	-0.788	-0.849	func_RCMAX
DGINST/out_reg[4]/CK (low)	2.017	1.514	-0.503	func_RCMAX

- Consider a design having 3 sequential endpoints:
 - setup_pin: Having a setup check with slack equal to -9.000
 - recovery_pin: Having a recovery check with slack equal to -8.000
 - both_setup_recovery_pin: Having both setup check (slack = -6.000) and recovery check (slack = -7.000)

In this case, the `report_constraint -late -all_violators` command will display the following output:

```
max_delay/setup
-----
End Point                Slack                Cause
-----
setup_pin f              -9.000                VIOLATED
both_setup_recovery_pin  -6.000                VIOLATED
-----
```

- The `report_constraint -check_type recovery -all_violators` command will display the following output:

```
Check type : recovery

report_cppr

```
report_cppr
[-help]
[-check_type {setup | hold | clock_gating_setup | clock_gating_hold |
clock_gating_pulse_width | data_setup | data_hold | recovery | removal | pulse_width |
clock_period | clock_separation | skew | no_change_setup | no_change_hold | time_borrow}]
-from pin_or_port
-to pin_or_port
[-from_clock clkname]
[-to_clock clkname]
[-early | -late]
[-view view_name]
[> filename]
```

Reports the clock reconvergence pessimism value at the common branching point of the early and late paths in the clock network of the specified data path.

The `report_cppr` command reports separate values for both opening and closing edges for paths with latches as destinations. If both source and destination flops are triggered by multiple clocks, then one report is generated for each separate clock.

When the software is in multi-mode multi-corner analysis mode, `report_cppr` reports the results for each active analysis view.

To use the `report_cppr` command, you must first set the following attributes:

- `timing_cppr_transition_sense`
- `timing_cppr_threshold_ps`

For more details, see [timing Category Attributes](#).

Parameters

-help	Prints out the command usage.
-------	-------------------------------

<pre>-check_type {setup hold clock_gating_setup clock_gating_hold clock_gating_pulse_width data_setup data_hold recovery removal pulse_width clock_period clock_separation skew no_change_setup no_change_hold time_borrow}</pre>	Reports the CPPR for the paths that end at the specified timing check. The following check types are reported when the software is in setup analysis mode: setup, pulse_width, clock_period, clock_gating_setup, clock_gating_pulse_width, data_setup, recovery, skew, clock_separation, time_borrow, and no_change_setup. The following check types are reported when the software is in hold analysis mode: hold, clock_gating_hold, data_hold, removal, and no_change_hold. If the software is in simultaneous setup and hold analysis mode, all of the check types listed above are reported.
<pre>> filename</pre>	Writes the report to the specified file name. If the file already exists, the software overwrites it. The <i>filename</i> parameter must be the last argument in the list. Note: To write a compressed report, add the .gz extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
<pre>-early</pre>	Reports the hold analysis clock re-convergence pessimism value. You can specify this parameter when the software is in hold analysis mode, or in simultaneous setup and hold analysis mode (set_db timing_enable_simultaneous_setup_hold_mode true). For more details, see timing Category Attributes.
<pre>-from pin_or_port</pre>	Reports the clock re-convergence pessimism value for paths starting from the specified clock pin of the source flop, or from the specified port.
<pre>-from_clock clkname</pre>	Reports the clock re-convergence pessimism value for paths with the specified triggering clock. Use this parameter when there is more than one clock triggering the source flop.

<code>-late</code>	Reports the setup analysis clock re-convergence pessimism value. You can specify this parameter when the software is in setup analysis mode, or in simultaneous setup and hold analysis mode (<code>set_db timing_enable_simultaneous_setup_hold_mode true</code>). For more details, see timing Category Attributes.
<code>-to pin_or_port</code>	Reports the clock re-convergence pessimism value for paths ending at the specified clock pin of the destination flop, or at the specified port.
<code>-to_clock clkname</code>	Reports the clock re-convergence pessimism value for paths with the specified capturing clock. Use this parameter when there is more than one clock capturing the destination flop.
<code>-view view_name</code>	Reports the clock re-convergence pessimism values for paths in the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

- The following command reports the clock re-convergence pessimism value for paths starting from the specified clock pin and ending at the specified destination pin:

```
tempus > report_cppr -from clk -to out2
```

```
Start Clock Pin: clk (Triggered by rising edge of clock CLK)
```

```
End Clock Pin: out2 (Triggered by rising edge of clock CLK)
```

```

report_critical_insts

```
report_critical_insts
[-help]
[-cost_type {worst_slack | total_slack | path_count | start_end_point_count}]
[-estimate]
[-include_sequential]
[-max_insts value]
[-max_slack slack]
[-out_file string]
[>> file ]
```

Reports instances in critical paths where the slack is less than the target slack.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>report_critical_insts</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man report_critical_insts</code>.
-cost_type	Specifies the criteria for choosing the critical instance. You can use the <code>-max_slack</code> and <code>-cost_type</code> parameters together to filter the paths to only those with slack worse than the specified <code>slack</code> value, then report the filtered set of paths based on the specified cost. <i>Default:</i> <code>worst_slack</code> Select one of the following options: <code>worst_slack</code>: Sets the criteria as the worst slack of all points that pass through an instance. <code>total_slack</code>: Sets the criteria as a sum of the slack of the end points. <code>path_count</code>: Sets the criteria as the sum of the total paths through the instance. <code>start_end_point_count</code>: Sets the criteria as the sum of the total start and end points connected to the instance.
-estimate	Generates a critical instance report based on the fast algorithm (linear-complexity) when cost type <code>=total_slack</code> to give a slightly pessimistic estimation that may include some false paths. Use this parameter in early design phase. <i>Default:</i> <code>false</code>

<code>file</code>	Writes the report to the specified file name. If the file already exists, the software overwrites it. Note: The file name must be the last argument in the list. <i>Default:</i> Displays the results in Tempus console window without being saved.
<code>-include_sequential</code>	Includes the sequential instances group in the output. <i>Default:</i> false (Reports combinatorial instances only.)
<code>-max_insts value</code>	Specifies the number of worst cost instances to report. <i>Default:</i> 20
<code>-max_slack slack</code>	Specifies the lower bound of the slack range. Only paths with slack worse than the specified <i>slack</i> value are reported. You can use the <code>-max_slack</code> and <code>-cost_type</code> parameters together to filter the paths to only those with slack worse than the specified <i>slack</i> value, then report the filtered set of paths based on the specified cost. <i>Default:</i> 0
<code>-out_file string</code>	Writes the report into the specified output file. Default: stdout

Command Order

Use this command after the timing graph is built by `time_design/opt_design`.

Examples

- The following command reports the critical instance information including sequential instances group for 5 worst cost instances:

```
tempus> report_critical_instance -sequential_insts -name_length 42 -max_insts 5
```

The following report is generated:

```
# -----
# Inst:combinatorial  Cell          Cost
# -----
p0042A82620          CKNHVTD4    -0.124
p0009A84488          CKND2HVTD2  -0.124
p0009A84792          IND2D1      -0.124
p0012A85164          CKNXHVTD1   -0.124
# -----
# Inst:sequential     Cell          Cost
# -----
dcache_/ram256        v11rbw_wsz10_hz8 -0.124

I1                    BUFX2      -0.117
I2                    BUFX2      -0.117
# -----
```

- The following command reports the critical instance information based on the worst slack of all points that pass through an instance, for paths with slack worse than -0.2:

```
tempus> report_critical_instance -cost_type worst_slack -max_slack -0.2
```

```
# -----
# Inst:combinatorial  Cell          Cost
# -----
I3                    BUFX2      -0.336
I10                   AND2X1     -0.336
```

- The following command reports the critical instance information based on the sum of the slack of the end points:

```
tempus> report_critical_instance -cost_type total_slack
# -----
# Inst:combinatorial    Cell        Cost      Start  End
# -----
I3                      BUFX2      -0.336     1      1
I10                     AND2X1     -0.336     2      1
I1                      BUFX2     -0.117     0      1
I2                      BUFX2     -0.117     0      1
# -----
```

- The following command reports the critical instance information based on the sum of the total paths through the instance:

```
tempus> report_critical_instance -cost_type path_count
# -----
# Inst:combinatorial    Cell        Cost      Start  End
# -----
I10                     AND2X1         4         2      1
I3                      BUFX2          2         1      1
I1                      BUFX2          2         0      1
I2                      BUFX2          2         0      1
# -----
```

- The following command reports the critical instance information based on the sum of the total start and end points connected to the instance:

```
tempus> report_critical_instance -cost_type start_end_point_count
# -----
# Inst:combinatorial    Cell        Cost      Start  End
# -----
I10                     AND2X1          2         1      1
I3                      BUFX2          2         1      1
I1                      BUFX2          2         1      1
I2                      BUFX2          2         1      1
# -----
```

- The following command reports the critical instance information based on the sum of the total start and end points connected to the instance, for paths with slack worse than -0.2:

```
tempus> report_critical_instance -cost_type start_end_point_count -max_slack -0.2
```

Related Commands

- `report_timing`

report_critical_nets

```
report_critical_nets  
[-help]  
[-max_slack double]  
[-number integer]  
[-view viewName]  
-out_file fileName
```

Generates a file containing a list of nets which have critical slack for the currently specified (setup or hold) timing analysis mode.

Parameters

-help	Prints a brief description that includes type and default information for each <code>report_critical_nets</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_critical_nets</code>
-max_slack <i>double</i>	Reports nets with slack less than the specified slack value.
-number <i>integer</i>	Restricts the number of critical nets to be reported to the first <i>integer</i> - most critical nets.
-out_file <i>fileName</i>	Specifies the name of report file.
-view <i>viewName</i>	Generates the report based on the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Command Order

Use this command after the timing graph is built.

Examples

- The following command reports nets with slack less than the specified slack value:

```
tempus > report_critical_nets -max_slack -1
```

Marking critical nets with target slack = -0.1ps.
Critical nets number = 7144.
- The following command generates a maximum slack report for the specified number of critical nets:

```
tempus > report_critical_nets -max_slack -1 -number 5
```

Marking critical nets with target slack = -0.1ps.
Critical nets number = 5.
- The following command generates a report named `critnet` that lists critical nets:

```
report_critical_nets -out_file critnet
```

report_critical_pins

report_critical_pins

`[-help]`
`-out_file fileName`

Performs slack analysis and writes the names of all critical terminals to the specified file. As a result, deterioration of setup slack can be avoided while the Innovus software repairs hold time violations.

Parameters

<code>-help</code>	Prints a brief description that includes type and default information for each <code>report_critical_pins</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_critical_pins</code>
<code>-out_file fileName</code>	Specifies the name of report file.

Command Order

Use this command after the timing graph is built by `time_design/opt_design`.

Examples

- The following attribute and command write the setup critical terminals into a file called `critTerm` :
`timing_analysis_check_type setup`
`report_critical_pins -out_file critTerm`

report_design

```
report_design
[-help]
[-view viewName]
[{> | >>} filename | -tcl_list]
[-early | -late]
```

Reports the minimum and/or maximum operating conditions and active design rules for the current design.

Both minimum and maximum operating conditions are available for on-chip variation analysis mode.

When simultaneous setup hold analysis mode is set to `on`, the minimum or maximum conditions can be reported using the `-early/-late` parameters.

Parameters

-help	Prints out the command usage.
{> >>} filename	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <i>filename</i> parameter must be the last argument in the list. The <i>filename</i> and <code>-tcl_list</code> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.

<code>-early -late</code>	The <code>-early</code> parameter reports minimum operating condition in <code>best_case_worst_case</code> or <code>ocv</code> analysis mode (<code>timing_analysis_type</code> attribute). The <code>-late</code> parameter reports maximum operating condition. The <code>-late</code> and <code>-early</code> parameters are mutually exclusive.
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. Note: The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify these parameters together.
<code>-view viewName</code>	Reports view specific operating conditions.

Examples

- The following command reports the operating conditions related to the view, `scan_slow_RCMAX`, along with the design rules:

```
report_design -view scan_slow_RCMAX
```

```
View : scan_slow_RCMAX
```

Design Property	Value	

Design Name	dtmf_recvr_core	

	MAX	MIN
Operating Condition Name	TypTyp_0.8V_25C	TypTyp_0.8V_25C
Process	1.000	1.000
Voltage	0.800	0.800
Temperature	25.000	25.000
Tree Type	balanced	balanced

Design Rule	Value

Max Transition	NA
Min Transition	NA
Max Capacitance	NA
Min Capacitance	NA
Max Fanout	NA
Min Fanout	NA

Related Commands

report_fanin

```
report_fanin
-to pin_port_net_list
[-trace_through {case_disable | user_disable | all}]
[-pin_levels numOfPinLevels]
[-view viewName]
[-nosplit]
[> | >> ] filename
```

Allows a cone traversal that is not tied to the timing graph, that is, not blocked by `set_disable_timing` and case analysis. By default, the trace matches the timing view and the reports generated using the `all_fanin` and `all_fanout` commands. The reports indicate whether disabled or case analysis arcs were traversed.

Parameters

<code>> >> filename</code>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file.
<code>-nosplit</code>	Specifies that reports with long names will not be split into multiple lines.
<code>-pin_levels numOfPinLevels</code>	Specifies the desired depth of the output.
<code>-trace_through {case_disable user_disable all}</code>	Allows traversal through disabled arcs. You can specify one of the following options: <code>case_disable</code>: Arcs which are disabled because of <code>set_case_analysis</code> are traversed but because of <code>set_disable_timing</code> are not traversed <code>user_disable</code>: Arcs disabled because of <code>set_disable_timing</code> are traversed but because of <code>set_case_analysis</code> are not traversed <code>all</code>: Trace through all arcs

<code>-to <i>pin_port_net_list</i></code>	Specifies a list or collection of pins, ports, or nets. A mixed list or heterogeneous collection is also allowed.
<code>-view <i>viewName</i></code>	Specifies disabled arcs in the specified view.

Examples

- The following command generates a report of the specified collection of pins along with the depth of the output for the specified view:

```
tempus > report_fanin -to FE_C674_ts_4 -pin_levels 3 -view scan_fast_RCMAX
```

```
Fanin Network for View: scan_fast_RCMAX
```

```
Fanin Network for Pin: FE_C674_ts_4/A

```

Source Pin	Sink Pin	Cell Type	Timing Sense	Arc	Case
				Disabled	Analysis

u1/Y	h0/A	(net)	-	-	-

u1/A	u1/Y	BUF_X2	positive_unate	-	-

in	u1/A	(net)	-	-	-

Related Commands

- `set_disable_timing`
- `set_case_analysis`
- `all_fanin`
- `all_fanout`

report_fanout

```
report_fanout
{-from pin_port_net_list | -clock_tree}
[-trace_through {case_disable | user_disable | all}]
[-pin_levels numOfPinLevels]
[-view viewName]
[-nosplit]
[{> | >> } filename]
```

Allows a cone traversal that is not tied to the timing graph, that is, not blocked by `set_disable_timing` and case analysis. By default, the trace matches the timing view and the reports generated using the `all_fanin` and `all_fanout` commands. The reports indicate whether disabled or case analysis arcs were traversed.

Parameters

<code>> >> filename</code>	When specified with <code>></code> , writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code> , writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file.
<code>-clock_tree</code>	Reports the fanout of the source pin, one after the other for all the clocks in the design.
<code>-nosplit</code>	Specifies that reports with long names will not be split into multiple lines.
<code>-pin_levels numOfPinLevels</code>	Specifies the desired depth of the output.

<code>-trace_through {case_disable user_disable all}</code>	Allows traversal through disabled arcs. You can specify one of the following options: <code>case_disable</code>: Arcs which are disabled because of <code>set_case_analysis</code> are traversed but because of <code>set_disable_timing</code> are not traversed. <code>user_disable</code>: Arcs disabled because of <code>set_disable_timing</code> are traversed but because of <code>set_case_analysis</code> are not traversed. <code>all</code>: Trace through all the arcs.
<code>-from pin_port_net_list</code>	Specifies a list or collection of pins, ports, or nets. A mixed list or heterogeneous collection is also allowed.
<code>-view viewName</code>	Specifies disabled arcs in the specified view.

Examples

- The following command reports details of a collection of pins at the desired depth of pin levels for the specified view:

```
tempus > report_fanout -from FE_C674_ts_4/A -pin_levels 4 -view scan_fast_RCMIN
```

Fanout Network for View: scan_fast_RCMIN

Fanout Network for Pin: FE_C674_ts_4/A

Source Pin	Sink Pin	Cell Type	Timing Sense	Arc Disabled	Case Analysis
FE_C674_ts_4/A	FE_C674_ts_4/Z	BUF_X32	positive_unate	-	-
FE_C674_ts_4/Z	MX_INST/p3A/B	(net)	-	-	-
FE_C674_ts_4/Z	FE_O402_ts_4/A	(net)	-	-	-
FE_C674_ts_4/Z	CS_INST/p21A/A3	(net)	-	-	-
MX_INST/p3A/B	MX_INST/p3A/Z	MUX2_X2	positive_unate	-	-
FE_O402_ts_4/A	FE_O402_ts_4/Z	BUF_X16	positive_unate	-	-
CS_INST/p21A/A3	TSP_INST/p2A/ZN	NOR4_X1	negative_unate	-	-
MX_INST/p3A/Z	FE_OFC105_n_94/A	(net)	-	-	-
FE_O402_ts_4/Z	M_128x16_ST/A[4]	(net)	-	-	-
TSP_INST/p2A/ZN	TST_CL/p3/A	(net)	-	-	-

- The following command reports details of a collection of pins at the desired depth of pin levels for disabled arcs:

```
tempus > report_fanout -from FE_C674_ts_4/A -pin_levels 2 -trace_through case_disable
```

```
Fanout Network for View: func_slow_RCMAx
```

```
Fanout Network for Pin: FE_C674_ts_4/A
```

Source Pin	Sink Pin	Cell Type	Timing Sense	Arc Disabled	Case Analysis
FE_C674_ts_4/A	FE_C674_ts_4/Z	BUF_X32	positive_unate	-	-
FE_C674_ts_4/Z	MX_INST/p3A/B	(net)	-	-	-
FE_C674_ts_4/Z	FE_O402_ts_4/A	(net)	-	-	-
FE_C674_ts_4/Z	CS_IST/p21A/A3	(net)	-	-	-

- Suppose arc seg1/u1 is disabled due to following constraint:

```
tempus> set_disable_timing -from A -to Y seg1/u1
```

```
tempus> report_fanout -from IN1 (command will show the following output):
```

```
Fanout Network for Port: IN1
```

Source Pin	Sink Pin	Cell Type	Timing Sense	Arc Disabled	Case Analysis
IN1	seg1/u1/A	(net)	-	-	-

- The following command will show the output below:

```
tempus> report_fanout -from IN1 -trace_through user_disable
```

```
Fanout Network for Port: IN1
```

Source Pin	Sink Pin	Cell Type	Timing Sense	Arc Disabled	Case Analysis
IN1	seg1/u1/A	(net)	-	-	-
seg1/u1/A	seg1/u1/Y	CLKBUF	positive_unate	Y	-
seg1/u1/Y	seg1/u2/A	(net)	-	-	-

Related Commands

- `set_disable_timing`
- `set_case_analysis`

- `all_fanout`

report_freq_violation

```
report_freq_violation
[-help]
[-detailed]
[-em_table_scale double]
[-em_type {avg | peak | rms | all}]
[-exclude_insts_file string]
[-include_insts_file string]
[-out_file string]
[-report_format integer]
[-transition {min | max}]
[-sort {name | freq | minDiff | maxDiff | minFreq | maxFreq}]
[-view string]
```

Runs electromigration (EM) analysis based on the frequency table defined in the Liberty library and generates a frequency violation report.

You must run the following commands prior to setting the `report_freq_violation` command:

- `write_tcf activityFile`
- `read_activity_file -format TCF activityFile`
- `propagate_activity`
- `read_activity_file -set_net_freq true -format TCF activityFile`
- `set_analysis_view -setup default_view_setup -hold default_view_hold`
- `set_db timing_analysis_check_type hold`

Note: If activity files are not defined, then the frequency can also be calculated on a pin by the clock period. There will also be a default frequency of 500M (toggle count 1e+9) if there is no clock phase on this pin.

Parameters

-help	Prints a brief description that includes type and default information for each <code>report_freq_violation</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man report_freq_violation.</code>
-detailed	Generates a detailed report containing information for instances with violations.

<code>-em_table_scale</code> <i>float</i>	Specifies the scale factor for EM table value. <i>Default:</i> 1.0
<code>-em_type {avg peak rms all}</code>	Specify the EM type. <i>Default:</i> avg
<code>-exclude_insts_file</code> <i>string</i>	Specifies an instance file that lists the names of instances to be excluded from the frequency violation report. Note: The instance file is a text file that contains a list of instances. Each instance name appears in one line in the file. The comments begin with "#". Leading or ending spaces in instance names are ignored.
<code>-include_insts_file</code> <i>string</i>	Specifies a file that lists the names of instances to be included in the frequency violation report. Note: The instance file is a text file that contains a list of instances. Each instance name appears in one line in the file. The comments begin with "#". Leading or ending spaces in instance names are ignored.
<code>-out_file fileName</code>	Specifies the report file for the violation data.
<code>-report_format</code> <i>integer</i>	Specifies a format for the violation report. The report details vary according to the selected report format. You can specify report formats 0, 1, or 2. For more information on the report formats, see Report Format section below. <i>Default:</i> 0
<code>-transition {min max}</code>	Specifies the minimum or maximum slew value. <i>Default:</i> min
<code>-sort {name freq minDiff maxDiff minFreq maxFreq}</code>	Sorts the instance-based frequency data by name, freq, minDiff, maxDiff, minFreq, and maxFreq. By default, the violation report is not sorted. You can use one of the following options: ◦ name: Name of a pin or arc. ◦ freq: Frequency value of a pin or arc. ◦ minDiff: Difference between freq and minFreq of a pin or arc. ◦ maxDiff: Difference between freq and maxFreq of a pin or arc. ◦ minFreq: Minimum frequency value of a pin or arc as defined in the frequency table. ◦ maxFreq: Maximum frequency value of a pin or arc as defined in the frequency table.

`-view viewName`

Specifies the view for which to generate the frequency violation report. Use this parameter when working with multi-mode multi-corner (MMMC) designs.

Example

- The following command reports instances that violate frequency constraints and lists them in the `freqViol.rpt` report file:

```
report_freq_violation -out_file freqViol.rpt
```

Report Format

The report formats are described below.

- Format 0

The following command generates a report providing details of `minFreq`, `Freq`, `Tran`, `Cap`, `Remark`, and `Arc/Pin` and directs the output to report file `summaryViol.rpt`:

```
report_freq_violation -out_file summaryViol.rpt -report_format 0
```

For example:

minFreq	Freq	Tran	Cap	Remark	Arc/Pin
5.985	1.009	0.0356	0.003103		tt0/data/r3/add_27/U1_1_6/Y

- Format 1

When `report_freq_violation -report_format` is set to 1, the report provides details as shown in the following example:

Status	Remark	freq	minFreq	maxFreq	Arc/Pin
[P]	*	1.009	5.985	5.995	tt0/data/r3/add_27/U1_1_6/Y

- Format 2

A detailed report is generated when `report_freq_violation -report_format` is set to 2, as shown in the following example:

Status	Remark	freq	minFreq	maxFreq	minTran	maxTran	minCap	maxCap
	Arc/Pin							
[P]	*	1.009	5.985	5.995	3.560e-02	3.790e-02	3.103e-03	3.103e-03
03	tt0/data/r3/add_27/U1_1_6/Y							

Where:

Status	Arc or pin status - F (fail), V (violation), P (pass), or ? (unknown)
Remark	Indicates whether the pin is a clock
freq	Working frequency of the arc or pin
minFreq	Minimum frequency value taken from the frequency table
maxFreq	Maximum frequency value taken from the frequency table
minTran	Minimum slew value
maxTran	Maximum slew value
minCap	Minimum capacitance load
maxCap	Maximum capacitance load
Arc/Pin	Name of the arc or pin

report_inactive_arcs

```
report_inactive_arcs
[-help]
[instance_port_obj]
[-exclude_type {const snipped disable library_disable global_disable conditional_disable
library_mode power_mode_disable}]
[-include_net_arcs]
[-include_when_cond]
[-type {const snipped disable library_disable global_disable conditional_disable library_mode
power_mode_disable}]
[-view view_name]
[> <filename[.gz]>]
[>> <filename[.gz]>]
[-delay_arcs_only | -check_arcs_only]
```

Reports information about disabled timing and timing check arcs in the design. Reports all arcs disabled due to user-specified exceptions such as [set_disable_timing](#) or [set_case_analysis](#), as well as information about arcs disabled by constant propagation during timing analysis, snipped loop arcs, and arcs disabled in the timing library.

Parameters

-help	Prints out the command usage.
instance_port_obj	Reports disabled timing arcs for the specified list of instances or ports. If you specify a list of instances, the software reports all disabled arcs of the specified cells. If you specify a list of ports, the software reports all disabled arcs directly connected to the ports. <i>Default:</i> Reports all disabled net and cell arcs.
-check_arcs_only	Lists only disabled check arcs. The <code>check_arcs</code> are disabled by using the <code>set_disable_timing</code> command. <i>Default:</i> Both disabled timing delay arcs and check arcs are listed.
-delay_arcs_only	Lists only disabled timing delay arcs.

<pre>-exclude_type {const snipped disable library_disable global_disable conditional_disable library_mode power_mode_disable}</pre>	Excludes the disabled arcs that belong to the specified category of disabled arcs. The valid options are: <code>const</code>, <code>snipped</code>, <code>disable</code>, <code>library_disable</code>, <code>global_disable</code>, <code>conditional_disable</code>, <code>library_mode</code>, and <code>power_mode_disable</code>.
<pre>-include_net_arcs</pre>	Includes disabled net arcs in the report.
<pre>-include_when_cond</pre>	Shows the <code>when_cond</code> of arcs in the output report.
<pre>-type {const snipped disable library_disable global_disable conditional_disable library_mode power_mode_disable}</pre>	Lists only the disabled arcs that belong to the specified category of disabled arcs. The <code>-type</code> options restrict the report to only those arcs that are disabled due to a particular timing analysis step, such as constant propagation, specified disables, or loop arc disables. The valid options are: • <code>const</code>: Propagated constant -- arcs disabled due to a constant value. The constant value can apply to one of the arc nets/pins, to side inputs which disable a condition for the arc, to nets that disable an active mode for the arc, or disable a default conditional arc. • <code>snipped</code>: Loop snipped arcs -- arcs automatically disabled by the Tempus software as part of a feedback loop. • <code>disable</code>: Defined by using the <code>set_disable_timing</code> command. • <code>library_disable</code>: Delay arc disabled due to library disables. These disables may be caused by the following conditions: ◦ Disables specified using the <code>set_disable_timing</code> command. ◦ The arc is an asynchronous arc and the attribute <code>timing_enable_preset_clear_arcs</code> is set to <code>false</code>.

	• <code>global_disable</code>: Lists the arcs that are disabled through user-specified global variable settings. • <code>conditional_disable</code>: Arcs disabled if a <code>when</code> condition is specified. There is no constant on sink or source pin and arc is disabled due to the <code>when</code> condition. • <code>library_mode</code>: Displays library mode of disabled arcs. • <code>power_mode_disable</code>: Allows reporting the arcs for which power mode is disabled.
<code>-view view_name</code>	Generates the report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.
<code>{> >>} filename</code>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <code>filename</code> parameter must be the last argument in the list. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.

Examples

- The following command lists disabled check arcs for the specified view:

```
tempus > report_inactive_arcs -check_arcs_only -view sn_fast_RMAX
```

```
-----
From          To          ArcType          Sense          Reason          View
-----
BT/se_0/CK    BT/se_0/D    hold_rising      non_unate      constant disabled sn_fast_RMAX
BT/se_0/CK    BT/se_0/D    setup_rising     non_unate      constant disabled sn_fast_RMAX
BT/se_0/RN    BT/se_0/RN    min_pulse_width  non_unate      constant disabled sn_fast_RMAX
BT/se_0/CK    BT/se_0/RN    removal_rising   non_unate      constant disabled sn_fast_RMAX
-----
```

- The following command reports all disabled arcs in the design:

```
tempus> report_inactive_arcs > Report
```

The following example shows the report generated:

```
-----
Flags :    const          propagated constant
          snipped        loop snipped arcs
          disable        set_disable_timing
          disable_clock_gating set_disable_clock_gating
          library_disable set_disable_cell_timing
          Missing_Phase   No Arc Phase Data
From       To       DisableType ArcType          Reason
-----
u8/CK ^    u8/D ^    const      hold_rising_clk_rise  u8/D = 1
u8/CK ^    u8/D v    const      hold_falling_clk_rise u8/D = 1
seg3/u12/A ^ seg3/u12/Y v disable    combinational        User Disable
-----
```

- When the software is in multi-mode multi-corner analysis mode, the report generated lists the disabled arcs by active analysis view, as shown in the following example:

```
-----
Flags : const propagated constant
snipped loop snipped arcs
disable set_disable_timing
disable_clock_gating set_disable_clock_gating
library_disable set_disable_cell_timing
Missing_Phase No Arc Phase Data
From       To       DisableType ArcType  Reason          View
-----
gscanmode ^ FE_O305_gmode/I ^ const      net_arc  gscanmode = 0  setup_view2
```

```
gscanmode v FE_0305_gmode/I v const      net_arc gscanmode = 0  setup_view2
gscanmode ^ FE_0305_gmode/I ^  const      net_arc gscanmode = 0  hold_view1
gscanmode v FE_0305_gmode/I v  const      net_arc gscanmode = 0  hold_view1
gscanmode ^ FE_0305_gmode/I ^  const      net_arc gscanmode = 0  hold_view2
-----
```

Related Commands

report_instance_library

```
report_instance_library  
[-out_file fileName]  
[-instance instanceName]  
[-view viewName | -delay_corner delayCornerName]  
[-power_domain domainName]  
[-early | -late]
```

Reports library related information for an instance(s). The report prints the following information about an instance:

- Instance name
- Cell type
- View name or delay corner
- Power domain name
- Library/Libset (early/late)
- Library file (early/late)
- Operating conditions
- Binding Status : Prints out the status for the matched voltage library available. If the user setting is `True`, then the binding status is not displayed.

Parameters

<code>-delay_corner <i>delayCornerName</i></code>	Specifies the delay corner from which an instance library is to be selected. If no delay corner is specified, then all the instance libraries will be printed.
<code>-early -late</code>	Specifies the library set (early/late) from which a library instance is to be printed. If either of these options are not specified then both the early and late library sets are used.
<code>-out_file <i>fileName</i></code>	Specifies the name of the output file. If no file is specified, the report will be printed on standard output file.

<code>-instance <i>instanceName</i></code>	Specifies the instance(s) for which the report is to be printed. If no instance is provided the report will print information of all the instances. The value of instance can be a list of regular expressions.
<code>-power_domain <i>domainName</i></code>	Specifies the power domain from which instance(s) are to be selected. Note: This parameter should be specified with <code>-delay_corner</code> or <code>-view</code> .
<code>-view <i>viewName</i></code>	Specifies the view from which instance library is to be selected.

Examples

- The following command displays the below information about instance `LIN_CONV_INST/F6A` for the specified view:

```
report_instance_library -instance LIN_CONV_INST/F6A -early -view scan_slow_RCMAX
```

```
Instance           : LIN_CONV_INST/F6A
Cell               : INV_X2
Analysis View      : scan_slow_RCMAX
Power Domain       : Default
Library/Libset(early) : F_lib_v1.0/libset_slow
Library File(early)  : /libs/F_lib_v1.0_worst.lib
Binding Status(early) : All PG Pins Voltage Match
Op Cond(early)      : P->1.000000, V->0.800000, T->25.000000 (TypTyp_0.8V_25C)
Cell Type          : gateCell
```

- The following command displays the below information about instance `FE_C674` for the specified delay corner:

```
report_instance_library -delay_corner delay_corner_slow_RCMAX -late
```

```
Instance           : FE_C674
Cell               : BUF_X32
Delay Corner       : delay_corner_slow_RCMAX
PowerDomain        : Default
Library/Libset(late) : F_lib_v1.0/libset_fast
Library File(late)  : /libs/F_lib_v1.0_typic
Binding Status(late) : All PG Pins Voltage Match
Op Cond(late)       : P->1.000000, V->0.800000, T->25.000000 (TypTyp_0.8V_25C)
Cell Type          : gateCell
```

Related Commands

- `check_timing_library_consistency`

report_ipd_configuration

```
report_ipd_configuration  
[-help]  
[-all]
```

Reports the rail sweep information and the software created voltage combinations, that is, the IPD views.

This command reports and indicates the valid voltage combinations along with the excluded voltage combinations.

Additionally:

- IPD views are named automatically as “ipd_view<count>”.
- “Excluded” column reports “yes” against the excluded voltage combinations - based on `set_ipd_rail_voltage -exclude_voltage_signatures settings`.

Parameters

-help	Prints out the command usage.
-all	Reports all the valid and excluded configurations. By default, the view exclusion status is not printed.

Examples

- A sample report is shown below, when the following command is used:

```
report_ipd_configuration

report_ipd_crossings

```
report_ipd_crossings  
[-help]  
[-all]  
[-cprpr_aware]  
[-from <pin_list>]  
[-from_power_domain <string>]  
[-out_file <file_name>]  
[-to <pin_list>]  
[-to_power_domain <string>]
```

Reports the IPD crossing information summary on the design. This command also provides details on the pins and instances that are part of these crossings.

Parameters

-help	Prints out the command usage.
-all	Reports detailed crossing information.
-cprpr_aware	Reports all the IPD crossings with CPPR awareness.
-from <pin_list>	Specifies the source pin for which crossing is to be reported.
-from_power_domain <string>	Specifies the source power domain for which crossing is to be reported.
-out_file <file_name>	Specifies the output file name - in case the output is to be redirected to a file.
-to <pin_list>	Specifies the sink pin for which crossing is to be reported.
-to_power_domain <string>	Specifies the sink power domain for which crossing is to be reported.

Examples

- The following output is generated by the `report_ipd_crossings` command:

```
tempus > report_ipd_crossings
```

```

report_lib_arcs

```
report_lib_arcs
[-help]
-arc <string>
[-fall]
[-nldm]
[-quiet]
[-rise]
[-lvf [-early]]
[-lvf [-late]]
[-moments [-mean_shift]]
[-moments [-std_dev]]
[-moments [-skewness]]
[-input_net_transition <float> | -constrained_pin_transition <float>]
[-input_net_transition <float> | -related_pin_transition <float>]
[-total_output_net_capacitance <float> | -constrained_pin_transition <float>]
[-total_output_net_capacitance <float> | -related_pin_transition <float>]
[-constrained_pin_transition <float> | -delay ] [-constrained_pin_transition <float> | -
transition ]
[-related_pin_transition <float> | -delay ]
[-related_pin_transition <float> | -transition ]
```

Reports the library arc data. The command also returns the data in a Tcl object, which can be used in scripts.

This command uses a collection of arcs as input, which can be queried using the `get_lib_arcs` command.

The units for the input and output data can be obtained using the `get_time_unit` and `get_capacitance_unit` commands.

Parameters

-help	Prints out the command usage.
-arc <string>	Specifies the arc(s) for which the report is to be printed.
-constrained_pin_transition <float>	Specifies the constrained pin slew (valid for constraint arcs) at which the parameters need to be reported. The slew units must be specified using the <code>get_time_unit</code> command.

<code>-delay</code>	Specifies if delay is to be reported.
<code>-early</code>	Specifies if early LVF data is to be reported. This parameter can be used only in conjunction with the <code>-lvf</code> .
<code>-fall</code>	Specifies if details of fall tables are to be reported.
<code>-input_net_transition</code> <float>	Specifies the slew at which the parameters need to be reported. The slew units must be specified using the <code>get_time_unit</code> command.
<code>-late</code>	Specifies if late LVF data is to be reported. This parameter can be used only in conjunction with the <code>-lvf</code> .
<code>-lvf</code>	Specifies if LVF data is to be reported.
<code>-mean_shift</code>	Specifies if the mean shift data is to be reported. This parameter can be used only in conjunction with the <code>-moments</code> .
<code>-moments</code>	Specifies if moments data is to be reported.
<code>-nldm</code>	Specifies if NLDM data is to be reported.
<code>-quiet</code>	Disables output to be displayed on the screen.
<code>-related_pin_transition</code> <float>	Specifies the related pin slew (valid for constraint arcs) at which the parameters need to be reported. The slew units must be specified using the <code>get_time_unit</code> command.
<code>-rise</code>	Specifies if details of rise tables are to be reported.
<code>-skewness</code>	Specifies if skewness data is to be reported. This parameter can be used only in conjunction with the <code>-moments</code> .
<code>-std_dev</code>	Specifies if standard deviation data is to be reported. This parameter can be used only in conjunction with the <code>-moments</code> .
<code>-</code> <code>total_output_net_capacitance</code> <float>	Specifies the load at which the parameters need to be reported. The load must be specified using the <code>get_capacitance_unit</code> command.
<code>-transition</code>	Specifies if the output slew is to be reported.

Examples

- The following command reports the library arc data containing mean shift rise tables:

```
tempus > report_lib_arcs -arc [get_lib_arcs -from cell_w/DFF/CK -to cell_w/DFF/Q] -
input_net_transition 0.08 /
      -total_output_net_capacitance 0.055 -mean_shift -rise -delay -moments -nldm
```

Units of Report:- Time: '1000ps', Capacitance: '1000fF'.

input_net_transition:0.080000, total_output_net_capacitance:0.055000

```
-----
| Index | Timing Arc | Value(s) | | | |

| -----
{{cell_rise 0.258} {rise_transition 0.216} {ocv_mean_shift_cell_rise NA}
{ocv_mean_shift_rise_transition NA}}
```

This command also returns the data in a Tcl object that can be parsed and used in scripts. A 3-Dimensional Tcl List will return the following information:

```
{{TableName Value} {TableName Value}} {{TableName Value} {TableName Value}}
```

Here, the first list (left column) indicates the Table-Value pair in one arc. The second list indicates the various tables present per arc. And the third list (last column) indicates the list of total arcs in the collection.

- The following command reports the slew and capacitance load:

```
tempus > set items [report_lib_arcs -arc [ get_lib_arcs -from sc_cmoslp/AO22X/clk -to
sc_cmoslp/AO22X /out1] /
-input_net_transition 0.003 -total_output_net_capacitance 0.021]
```

Units of Report:- Time: '1000ps', Capacitance: '1000fF'.

input_net_transition:0.003, total_output_net_capacitance:0.021

```

report_min_pulse_width

```
report_min_pulse_width
[-help]
[-clock <object_list>]
[-net]
[-path_type {summary | short | full_clock}]
[-pins <object_list>]
[-tcl_list]
[-verbose]
[-view <view_name>]
[-violation_only]
[-waveform_aware_type {regular | waveform_aware | both}]
[> <filename[.gz]>]
[>> <filename[.gz]]
```

Reports a set of minimum pulse width violations on pins and ports on the clock network. The report shows the required pulse width, the actual pulse width, and by how much the constraint is violated or met. This is reported separately for sequential elements and instances on the clock tree.

You can customize pulse width reporting format by using the [report_timing_format](#) attribute.

The report header shows clock edge information to make it more intuitive for clock style checks.

Parameters

-help	Prints out the command usage.
-clock <object_list>	Specifies a set of clocks to for which to report the minimum pulse width.

<pre>{> >>} filename</pre>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <code>filename</code> parameter must be the last argument in the list. The <code>filename</code> and <code>-tcl_list</code> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
<pre>-net</pre>	Reports the net arcs. This parameter can be specified with the <code>-path_type full_clock</code> option only.
<pre>-path_type {summary short full_clock}</pre>	Specifies the type of report to generate. <i>Default:</i> <code>summary</code> • <code>summary</code>: Generates a summary report for each pulse width check that shows the required width, the actual width, and the resulting slack. • <code>short</code>: Generates a path report for each pulse width check that lists the latency of each edge of the pulse as a single lumped value, instead of reporting a detailed path report. • <code>full_clock</code>: Generates a path report for each pulse width check that shows the detailed pin-to-pin path for each edge of the pulse. Note: The <code>-path_type full_clock</code> parameter may cause an increased runtime. In that case you can use the <code>-path_type short</code> parameter.

<code>-pins <i>object_list</i></code>	Specifies a set of ports and pins on the clock network. If this list is not specified, then the report contains all the pins and ports in the current design.
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.
<code>-verbose</code>	Provides detailed information about minimum pulse width calculations. Note: This parameter is obsolete. The parameter still works in this release, but to ensure compatibility with future releases, use the <code>-path_type</code> parameter instead.
<code>-view <i>view_name</i></code>	Generates the report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.
<code>-violation_only</code>	Reports only the negative slack minimum pulse width violations.
<code>-waveform_aware_type {regular waveform_aware both}</code>	Reports the waveform-aware pulse width checks. You can specify the following options: <code>waveform_aware</code>: Reports only the waveform-aware pulse width checks. <code>both</code>: Reports waveform-aware as well as regular pulse width checks. <code>regular</code>: Reports regular pulse width checks. This is the default setting.

Examples

- The following command reports minimum pulse width for the specified clock and view:

```
tempus > report_min_pulse_width -clock m_spi_clk -view slow_RCMIN
```

```
-----  
                        SEQUENTIAL CLOCK PULSE WIDTH
```

report_mode

```
report_mode  
[-help]  
inst_list  
[-view viewName]
```

Reports the status of library modes associated with a specified instance. The report includes the status of each mode and its condition, for each mode group defined in the timing library.

Parameters

-help	Prints out the command usage.
inst_list	Generates a report for the specified instances.
-view viewName	Reports the status of library modes in the specified active analysis view. Default: Reports the status of library modes in all active analysis views.

Examples

- The following command activates the `tst_mode_disable` library mode for instances of `i_ram`:

```
tempus> set_mode tst_mode_disable [get_cells i_ram]
```

- The following command sets the active setup and hold analysis views:

```
tempus> set_analysis_views -setup {v1 v2} -hold {v3}
```

- The following command reports the status of all modes associated with `m4k_top`:

```
tempus> report_mode m4k_top
```

```
-----  
Mode Group tst_mode of m4k_top  
-----  
Mode Name      Status    Condition    View Name

- `set_mode`

report_nets

```
report_nets
[-help]
[-min_fanout int]
[-max_fanout int]
{-net list_of_net_name_or_id | -pin list_of_pin_name_or_id}
[-hier]
[-tcl_list]
[> | >>] filename
```

Reports the net information on the current module. The information includes the net name, the number of source pins, sink pins and bidirectional pins on the net, wire capacitance, and total capacitance.

Electrical information such as pin capacitance, and wire capacitance with which the net is associated are also included.

Use the `-pin` option to report the net that is connected to the specified pin (or port). Both `-net` and `-pin` cannot be specified at the same time. The net (or pin) names can be hierarchical names that are unique relative to the top cell.

This command only searches for the defined nets and does not modify any object in database.

Parameters

-help	Prints out the command usage.
> >> filename	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <i>filename</i> parameter must be the last argument in the list. The <i>filename</i> and <code>-tcl_list</code> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.

<code>-hier</code>	Reports all of the nets in the design hierarchy. Without this argument, only the nets in the current level of hierarchy are reported.
<code>-max_fanout int</code>	Reports the net whose number of fanouts is less than or equal to the maximum number specified by <i>integer</i> .
<code>-min_fanout int</code>	Reports the net whose number of fanouts is greater than or equal to the minimum number specified by <i>integer</i> .
<code>-net list_of_net_name_or_id</code>	Reports the set of nets on the list of net names. This argument cannot be specified at the same time as <code>-pin</code> . If neither <code>-net</code> or <code>-pin</code> is specified, all nets are listed by default. Note: This argument also reports the capacitance of the net and the input pins.
<code>-pin list_of_pin_name_or_id</code>	Reports the set of nets to which the pins on the list <i>list_of_pin_name_or_id</i> are connected. This argument cannot be specified at the same time as <code>-net</code> .
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for extracting information from the report in a Tcl program.

Examples

- The following command reports details of the specified set of nets:

```
tempus > report_nets -net FE_data_out_1
```

```
Net Name           : FE_data_out_1
Number of Sources  : 1
Number of Sinks    : 1
Number of Bidis    : 0
Source of parasitics : Detailed Spief
Net Capacitance    : 0.000
Total Capacitance  : 0.001
```

```

clk(D) (P) (fast_RCMAX)								

- Control the `report_nets` table fields, such as setting the minimum and maximum column width using the `set_table_style` command. The table names are `report_nets_source_table`, `report_nets_sink_table`, `report_nets_summary_table`, `report_nets`, and `report_nets_header`.
- The following command sets an indentation of six columns for the table and disables printing of the first column:

```
set_table_style -name report_nets_source_table -indent 6 -max_widths {0,}
```

report_nets

- The format of the `report_nets` report is the same for all the examples, as shown in the first example. The following command reports information about net named `in`, as shown in the following example:

```
report_nets -net n5
```

Net Name : n5

Number of Sources : 1

Number of Sinks : 1

Number of Bidis : 0

Source of parasitics : Wireload model(.lib None Generated)

Net Capacitance : 0.000

Total Capacitance : 0.011

- `report_timing`

report_parasitic_coordinate_transforms

```
report_parasitic_coordinate_transforms  
[-help]  
[-user]
```

Reports the transformations applied to the hierarchical SPEF instances to translate the hierarchical locations given in the SPEF files to the flat locations for the design.

Parameters

-help	Prints a brief description that includes type and default information for each <code>report_parasitic_coordinate_transforms</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_parasitic_coordinate_transforms</code> .
-user	Reports user-specified transforms.

Examples

The following command reports user-specified transforms:

```
create_parasitic_coordinate_transform -inst ARB_INST -x_offset 16.8 -y_offset 20.5 -orient  
R0 -x_block_origin 0 -y_block_origin 0
```

```
report_parasitic_coordinate_transforms -user
```

#cell	x_offset	y_offset	orient	x_block_origin	y_block_origin	source
hinst						
arb	16.8	20.5	R0	0	0	User

report_path_based_aocv_derate

```
report_path_based_aocv_derate
  [-help]
  [-aocv_derate_only]
  [-delay_corner delayCornerName]
  [-derate_mode {worst_slack | worst_derate}]
  [-early]
  [-include_clock_derate]
  [-late]
  [-max_slack val]
  [-max_paths integer | -max_points integer]
  [-nworst worst_entries]
  [-retime {aocv | aocv_path_slew_propagation}]
  [-retime_mode {path | exhaustive}]
  [> filename [.gz]]
  [>> filename [.gz]]
```

Parameters

<code>-help</code>	Prints out the command usage.
<code>-aocv_derate_only</code>	Allows AOCV reporting only.
<code>-delay_corner <i>delayCornerName</i></code>	Specifies name of the delay corner.
<code>-derate_mode {worst_slack worst_derate}</code>	Specifies the derating mode. <i>Default:</i> <code>worst_derate</code>
<code>-early</code>	Specifies derates for early paths.
<code>-include_clock_derate</code>	Includes the clock derate values.
<code>-late</code>	Specifies derates for late paths.
<code>-max_paths <i>integer</i></code>	Reports derates based on the specified number of paths.
<code>-max_points <i>integer</i></code>	Reports derates based on the specified number of endpoints.
<code>-max_slack <i>val</i></code>	Reports the upper bound value of the reported slack.
<code>-nworst <i>worst_entries</i></code>	Reports the derates based on the specified number of worst paths per end point.
<code>-retime {aocv aocv_path_slew_propagation}</code>	Reanalyzes the specified set of paths using the specified method. <i>Default:</i> <code>aocv</code>
<code>-retime_mode {path exhaustive}</code>	Defines the retime mode as <code>path</code> or <code>exhaustive</code> .
<code>> <i>filename[.gz]</i></code>	Redirects output to the specified file.
<code>>> <i>filename[.gz]</i></code>	Redirects output to the specified file.

Examples

- The following command reports derates based on the given number of paths for the specified delay corner:

```
tempus > report_path_based_aocv_derate -delay_corner DC_wc -max_paths 1
```

```
INFO: Path Based Analysis (PBA) performed on total '1' paths
```

```
set_timing_derate -late -delay_corner DC_wc -data -rise 1.600 [get_cells { i0 }]
```

```
set_timing_derate -late -delay_corner DC_wc -data -rise 1.000 [get_cells { i1 }]
```

```
set_timing_derate -late -delay_corner DC_wc -data -rise 1.000 [get_cells { sub_inst1/i1  
}]
```

- The following command reports clock derates for the specified delay corner:

```
tempus 8> report_path_based_aocv_derate -delay_corner DC_wc -include_clock_derate
```

```
INFO: Path Based Analysis (PBA) performed on total '4' paths
```

```
set_timing_derate -late -delay_corner DC_wc -data -rise 1.600 [get_cells { i0 }]
```

```
set_timing_derate -late -delay_corner DC_wc -data -rise 1.000 [get_cells { i1 }]
```

```
set_timing_derate -late -delay_corner DC_wc -data -fall 1.014 [get_cells { i2 }]
```

```
set_timing_derate -early -delay_corner DC_wc -clock -rise 0.820 [get_cells { i3 }]
```

Related Commands

- [report_timing](#)

report_path_exceptions

```
report_path_exceptions
[-help]
[-all]
[-early | -late]
[-ignored]
[-view view_name]
[{> | >>} filename | -tcl_list]
```

Generates a report about path exceptions specified using the `set_false_path`, `set_min_delay`, `set_max_delay` and `set_multicycle_path` commands.

By default, the `report_path_exceptions` command only reports activated path exceptions. To report only the path exceptions that have been ignored by timing analysis, specify the `-ignored` parameter.

If more than one path exception is applied on a timing path, multiple path exceptions that match a given path are prioritized. The adjustment on the path honors the path exception with the highest priority.

When the software is in multi-mode multi-corner timing analysis mode, the report generates path exception information for every active analysis view.

The `report_path_exceptions` command output also includes 2 columns that show the file name and line number. The report output shows the exact file name and line number of the applied/ignored constraints. The compressed constraints will be decompressed first and then shown as individual constraints as written in the SDC file.

Parameters

-help	Prints out command usage.
-all	Reports all the applied and ignored path exceptions.

<pre>{> >>} filename</pre>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <code>filename</code> parameter must be the last argument in the list. The <code>filename</code> and <code>-tcl_list</code> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
<pre>-early -late</pre>	Generates the path exception report for either early paths or late paths. <i>Default:</i> Generates a report based on the current timing analysis mode.
<pre>-ignored</pre>	Reports only the path exceptions that have been ignored by timing analysis. This parameter can be used for debugging constraints that may be ineffective or incorrectly entered. A path exception may be ineffective if it is covered by, or overridden by, another path exception. For example: <pre>set_false_path -to OUT set_multicycle_path -to OUT 2</pre> In the above situation, the <code>set_multicycle_path</code> command would be ignored because the false path has a higher priority.
<pre>-tcl_list</pre>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together.

`-view view_name`

Generates a path exception report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

- The following command generates an exception report of late paths for the specified view:

```
tempus > report_path_exceptions -view scan_slow_RCMAx -late
```

From	To	Late	View Name
scan_se		add 1	scan_slow_RCMAx
tst_mode	refclk	false	scan_slow_RCMAx
SPI/bit_reg[3]/RN	SPI/bit_reg[1]/RN	false	scan_slow_RCMAx

- The following commands shows that a false path has priority over cycle addition on the same path:

```
tempus > set_false_path -from seg1/u3/q -to seg1/u9/d
tempus > set_multicycle_path -from seg1/u3/Q -to seg1/u9/D 2
tempus > report_path_exceptions -ignored
```

From	To	Early	Late
seg1/u3/Q	seg1/u9/D	false ignored	false ignored
seg1/u3/Q	seg1/u9/D	-	add 1 ignored
seg1/u3/Q	seg1/u9/D	add 0 ignored	-

The following command shows how edges are handled:

```
tempus > set_false_path -rise_from {IN1} -through {OUT1}
tempus > set_false_path -rise_from {IN1 IN2} -fall_to {OUT1}
tempus > set_false_path -rise_from {IN1}
tempus > report_path_exceptions -ignored
```

From	Through	To	Early	Late
^ IN1 IN2	-	v OUT1	false ignored	false ignored
^ IN1	OUT1	-	false ignored	false ignored

```
tempus > report_path_exceptions -early
```

From	Through	To	Early
------	---------	----	-------

```

^ IN1      -      -      false
-----

tempus > report_path_exceptions -late
-----
From      Through  To      Late
-----
^ IN1      -      -      false
-----

```

When the software is in multi-mode multi-corner timing analysis mode, the software generates path exception information for every active analysis view:

```

tempus > set_analysis_view -setup {setup1 setup2} -hold {hold1 hold2}
tempus > report_path_exceptions

```

```

-----
From              Early    Late      View
                  Name
-----
test_mode reset   false           setup2
test_mode reset   false           setup1
test_mode reset           false    hold1
test_mode reset           false    hold2
-----

```

You can specify the `-view` parameter to generate a report only for a specific active analysis view:

```

tempus > report_path_exceptions -view setup1
-----
From      Early    Late      View
                  Name
-----
test_mode  reset    false    setup1
-----

```

Related Commands

- [report_timing](#)

report_path_groups

```
report_path_groups
[-help]
[-name group_name]
[{> | >>} filename | -tcl_list]
```

Generates a report that lists the names of all path groups with the corresponding paths.

Parameters

-help	Prints out the command usage.
{> >>} filename	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <i>filename</i> parameter must be the last argument in the list. The <i>filename</i> and <i>-tcl_list</i> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the .gz extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
-name group_name	Limits the report to the specified path group. <i>Default:</i> All path groups are reported.

`-tcl_list`

Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation.

The `-tcl_list` and *filename* parameters are mutually exclusive; you cannot specify them together.

Examples

- The following command generates a report that shows details of the specified path group:

```
tempus > set_path_group -name path1 -through CF_PS_PD_142/NS
```

```
tempus > report_path_groups -name path1
```

```
-----
Through          Group Name    View Name
-----
CF_PS_PD_142/NS  path1          setup_gs_mC
-----
```

- The following command shows a sample report:

```
tempus> report_path_groups
```

```
-----
From    To          Group Name
-----
CLK1    seg1/u3/D  path1
-----
```

Related Commands

- `set_clock_groups`

- `get_path_groups`
- `group_path`

report_pg_net_group

```
report_pg_net_group  
[-help]  
[-expand]  
[-group <name>]
```

Reports the output of the `create_pg_net_group` command settings. The output indicates the PG net groups created in the design and the PG nets associated with these groups.

Parameters

-help	Prints out the command usage
-group <name>	Specifies a list of power nets associated with the specified group.

Examples

- The following command shows the report output of the previously created group PG1:

```
tempus > report_pg_net_group  
  
create_pg_net_group -name PG1 -pg_nets {VDD_top VDD1 VDDalive VSS}
```

- The following command shows the PG nets associated with the PG net group PG1:

```
tempus> report_pg_net_group -group PG1  
  
VDD1 VDD_top VDDalive VSS
```

Related Commands

- `create_pg_net_group`
- `create_ipd_configuration`
- `report_ipd_configuration`
- `write_ipd_scope`
- `read_ipd_scope`
- `set_ipd_rail_voltage`
- `report_ipd_crossings`

Related Information

- For more information, refer to the [Inter Power Domain \(IPD\) Analysis](#) chapter in the *Tempus Stylus User Guide*.

report_ports

```
report_ports
[-type {[input] | [source_insertion] | [insertion] | [clock_root]
| [uncertainty] | [arrival] | [required] | [external] | [clk_arrival]
| [port_cap] | [fanout_load] | [fanout_load_limit] | [drive_resistance]
| [drive_cell] | [slew_time] | [slew_limit] | [constant] | external_detail
| drive_resistance_detail}]
[-include_pins]
[-pins port_name_list]
[-view view_name]
[> filename | -tcl_list]
```

Reports timing constraints on ports. By default, the command reports all timing constraints on all ports of the current module.

The direction (*DIR*) column of the generated report can contain one of the following abbreviations:

- `IN` indicates that the pin is an input pin.
- `OUT` indicates that the pin is an output pin.
- `INTL` indicates that the pin is an internal pin (a pin inside the instance boundary).

The *Clock Name* column of the report can contain the following symbols:

- `D` indicates it is a data signal in the clock domain.
- `C` indicates it is a clock signal in the clock domain.
- `P` indicates it is a positive phase.
- `N` indicates it is a negative phase.
- Asterisk (*) indicates there is a timing exception associated with the signal.

Note: Currently, it is not possible to expand the asterisk to determine which exception is associated with the reported timing phase.

Parameters

> <i>filename</i>	Writes the report to the specified file name. If the file already exists, the software overwrites it. The <i>filename</i> parameter must be the last argument in the list. The <i>filename</i> and <i>-tcl_list</i> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <i>.gz</i> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
-include_pins	Reports timing constraints on instance pins, as well as on ports. <i>Default:</i> Reports timing constraints on ports only.
-pins <i>port_name_list</i>	Specifies the pins or ports to be reported. Pins can be specified by name, or by object ID in a Tcl list.
-tcl_list	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The <i>-tcl_list</i> and <i>filename</i> parameters are mutually exclusive; you cannot specify them together.
-type { <i>assertion_type</i> <i>assertion_type_list</i> }	Generates the report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.
-view <i>view_name</i>	Specifies the view name.

Examples

- The following command reports details of the specified list of pins:

```
tempus > report_ports -pins scan_en
-----
-
                                     Early           Late
-----
-
```

Pin Name	Dir	Assertion	Clock Name	Rise	Fall	Rise	Fall

[-nosplit]  
[-view]  
[> file_name]  
[>> file_name]
```

Reports reference cell usage statistics.

The command reports the unit area, library name, and total count of the reference cells. By default, the report is sorted in the order of number of instances.

Parameters

-help	Prints out the command usage.
-flat	Disables printing of hierarchical instances.
-nosplit	Generates the report in no split mode.
-view	Generates the report for the specified analysis view.
> file_name	Specifies the name of write mode file name.
>> file_name	Specifies the name of the append mode file name.

Examples

- The following command displays the report for the specified view:

```
report_reference -view func_slow_RCMIN
```

```
Design : dtmf_recvr_core
```

```
Attributes :
```

```
c - combinational (standard cell)
```

```
sq - sequential (standard cell)
```

```
m - macro
```

```
h - hierarchical
```

```
b - blackbox
```

Reference	Library	Unit Area	Count	Total Area
Attributes				

AND3_X4 c	FrPK45_lib_v1.0	1.330	8	10.640
SDFX_X1 sq	FrPK45_lib_v1.0	6.916	10	69.160
AOI22_X4 c	FrPK45_lib_v1.0	2.128	9	19.152
NAND3_X1 c	FrPK45_lib_v1.0	1.064	87	92.568

report_slack_histogram

```
report_slack_histogram  
[-help]  
[-compact]  
[-early]  
[-in_file string]  
[-late]  
[-max_slack float]  
[-min_slack float]  
[-out_file string]  
[-plus_non_violating]  
[-retime {aocv | ssta | path_slew_propagation | aocv_path_slew_propagation}]  
[-retime_mode {path | exhaustive}]  
[-step float]  
[-target_slack float]  
[-view string]
```

Generates a histogram of end-point slacks.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-compact</code>	Specifies the compact column report format. This format removes any histogram rows, which have a count of 0.
<code>-early</code>	Specifies early mode analysis for computing histogram.
<code>-in_file string</code>	Specifies input filename to be used for generating histogram. When the <code>-in_file</code> parameter is specified, the <code>report_slack_histogram</code> command generates reports using data from the specified file. <i>Default:</i> The software will generate this data with default <code>max_paths</code> limit.
<code>-late</code>	Specifies late mode analysis for computing histogram.
<code>-max_slack float</code>	Specifies the upper slack limit for the generated report. <i>Default:</i> 0
<code>-min_slack float</code>	Specifies the lower slack limit for the generated report. <i>Default:</i> Worst negative slack
<code>-out_file string</code>	Specifies the result filename. <i>Default:</i> Displays the report on the Tempus console.
<code>-plus_non_violating</code>	Specifies to include the non-violating slack values.
<code>-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation}</code>	Re-analyzes the specified set of paths using the specified method.
<code>-retime_mode {path exhaustive}</code>	Re-analyzes the specified set of paths using the specified method.
<code>-step float</code>	Specifies the precision for slack histogram. <i>Default:</i> 0.5ns
<code>-target_slack float</code>	When specified, the slack histogram is centered around the defined target slack value.
<code>-view string</code>	Writes out slack histograms for the specified view. If you do not specify this option, the command outputs details for all the views.

Examples

- The following command reports the lower slack limits along with the non-violating slack values:

```
report_slack_histogram -compact -min_slack -10 -plus_non_violating
```

```
-----
```

Slack Range (ns)	Count	Sum
+-----+-----+-----+		
(-9.949 ~ -9.449]	15	15
(-9.449 ~ -8.949]	12	27
(-8.949 ~ -8.449]	18	45
(-8.449 ~ -7.949]	16	61

```
-----
```

- The following command reports the upper slack limits for the specified view:

```
report_slack_histogram -max_slack -20 -step 0.5 -view func_fast_RCMAx
```

```
-----
```

Slack Range (ns)	Count	Sum
+-----+-----+-----+		
(-21.182 ~ -21.000]	7	7
(-21.000 ~ -20.500]	2	9
(-20.500 ~ -20.000]	5	14

```
-----
```

- The following command shows a report for the specified target slack value:

```
report_slack_histogram -target_slack -21
```

```
-----
```

Slack Range (ns)	Count	Sum
+-----+-----+-----+		
(-22.239 ~ -22.000]	7	7
(-22.000 ~ -21.500]	2	9
(-21.500 ~ -21.000]	5	14
(-21.000 ~ -20.500]	2	16
(-20.500 ~ -20.000]	3	19

```
-----
```

Related Commands

- `write_global_slack_report`

report_socv_interconnect_variation

```
report_socv_interconnect_variation
[-help]
[-delay_corner string]
[-power_domain string]
```

Reports the RC variation multiplier data provided in the SOCV files.

Parameters

-help	Prints out the command usage.
-delay_corner string	Specifies the name of the delay corner.
-power_domain string	Specifies the name of the power domain.

Examples

- The following command generates the below output for the specified delay corner:
report_socv_interconnect_variation -delay_corner delay_corner_FUNC_PVT_ss_0p72_m40_rcmax

```
Delay Corner: delay_corner_FUNC_PVT_ss_0p72_m40_rcmax

report_socv_library

```
report_socv_library  
[-help]  
[-categories string]  
[-coverage_verbose]  
[-list_not_annotated]  
[-library_set string | { -delay_corner string [ -power_domain string ] } | { -view string [-  
power_domain string]}]  
[-libraries string | -lib_cells string]  
{-coverage}
```

Reports the coverage of SOCV library(s) loaded in the design.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-categories string</code>	Allows you to control what types of table data to check delay arcs, transition arcs, and check arcs. <i>Default:</i> all
<code>-coverage</code>	Controls for reporting coverage library data.
<code>-coverage_verbose</code>	Generates a detailed report table per cell.
<code>-delay_corner string</code>	Checks all the libraries defined in the specified delay corner.
<code>-lib_cells string</code>	Specifies the library cells. The allowed format is \u201clibrary/cell\u201d name or pattern or collection. This will typically be done to drill-down debugging of problems.
<code>-libraries string</code>	Allows you to select the library. If <code>-library_set</code> , <code>-delay_corner</code> , or <code>\u2013view</code> is not specified then all libraries matching the library name across the MMMC configuration will get checked.
<code>-library_set string</code>	Checks all the libraries defined in the specified library set.
<code>-list_not_annotated</code>	Allows you to control the types of table data to check delay arcs, transition arcs, and check arcs. <i>Default:</i> all
<code>-power_domain string</code>	Checks the specified power domain.
<code>-view string</code>	Checks all the delay corners associated with the specified view.

Examples

- The following command displays the SOCV configuration summary report, which shows the coverage type for the specified libraries:

```
report_socv_library -coverage -delay_corner delay_corner_slow_RCMIN -categories
transition
```

```

report_statistical_timing_derate_factors

```
report_statistical_timing_derate_factors
[-help]
[-derate_cell]
[-derate_cell_check]
[-derate_net]
[-max_slack float]
[-path_based_ssta]
[-path_group groupname_list]
[-ssta_view ssta_view_name]
[-sta_view sta_view_name]
[-type {arrival_time_based | slack_time_based}]
[-early | -late ]
[-clock_factor | -data_factor]
[-max_paths integer | -max_points integer]
```

Reports design-specific OCV factors. The scaling factor (hold or setup) is computed either by using the arrival time or slack time approach.

Parameters

<code>-clock_factor -data_factor</code>	Specifies if the user-defined factor value is for clock or data. If you specify the <code>-clock_factor</code> parameter, then the <code>-data_factor</code> parameter is calculated by the software, and vice versa. These parameters are applicable to type <code>slack_time_based</code>. Note: The <code>-clock_factor</code> parameter and the <code>-data_factor</code> parameter are mutually exclusive. You cannot specify them together.
<code>-derate_cell</code>	Applies user-specified scaling factors on cell delays.
<code>-derate_cell_check</code>	Applies user-specified scaling factors on timing checks.
<code>-derate_net</code>	Applies user-specified scaling factors on net delays.
<code>-late -early</code>	Specifies early or late mode analysis. Default is <code>late</code> .

<code>-max_paths</code>	Reports the specified number of worst paths in the design, regardless of the endpoint.
<code>-max_points <i>integer</i></code>	Reports the worst path that is found to each endpoint up to the number specified by the <code>-max_points</code> option.
<code>-max_slack <i>float</i></code>	Reports only those paths with slack equal to or less than the specified float value.
<code>-path_based_ssta</code>	Enables generation of the statistical OCV factor using path based SSTA analysis.
<code>-path_group <i>groupname_list</i></code>	Considers only the path contained in the groups in the specified <i>groupname_list</i> for computing the statistical timing derate factor.
<code>-ssta_view <i>ssta_view_name</i></code>	Specifies view for SSTA run.
<code>-sta_view <i>sta_view_name</i></code>	Specifies view for STA run.
<code>-type arrival_time_based slack_time_based</code>	Specifies if the OCV factor needs to be generated using the arrival time or slack time approach. In the arrival time approach, the SSTA arrival time values are used to compute the statistical OCV factor for clock and data. In the slack time approach, the STA and SSTA slacks are used to generate the statistical OCV factor for either clock or data depending on whether you specify the factor for data or clock. <i>Default:</i> <code>arrival_time_based</code> You can use the <code>-type arrival_time_based</code> parameter with the following parameters only: ● <code>-late</code> ● <code>-early</code> ● <code>-path_based_ssta</code>

You can use the `-type slack_time_based` parameter with the following parameters only:

- `-ssta_view`
- `-sta_view`
- `-late`
- `-early`
- `-clock_factor`
- `-data_factor`
- `-derate_cell`
- `-derate_net`
- `-derate_cell_check`
- `-max_paths`
- `-max_slack`

Examples

- The following command enables SOCV analysis mode:

```
tempus> set_db timing_analysis_socv true
```

The following command reports OCV factors that are generated using the arrival time:

```
tempus> report_statistical_timing_derate_factors -type arrival_time_based
```

```
-----
p out waveforms (MEM=2971.51 CPU=0:00:00.0 REAL=0:00:00.0)

-----

```

- The following example computes the factors for setup analysis using the arrival time based approach:

```
report_statistical_timing_derate_factors -type arrival_time_based -late
```

- The following example computes the data factor for setup analysis using the slack time based approach applying a user defined clock factor of 0.95:

```
report_statistical_timing_derate_factors -type slack_time_based -ssta_view viewname -
sta_view viewname -clock_factor 0.95
```

- The following example computes the clock factor for hold analysis using the slack time based approach applying a user defined data factor of 1.05:

```
report_statistical_timing_derate_factors -type slack_time_based -ssta_view viewname -
sta_view viewname -data_factor 1.05 -early
```

report_timing

```

Generates a timing report that provides information about the various paths in a design.

The reports typically contain data on the delay through the entire path. The start node and the end node of each path is identified.

The timing report contains the following information:

- The slack times of the arriving signal at the end node
- The start node
- The associated transitions
- The signal required times and the actual signal arrival times
- Summary of propagated vs ideal status of launching and capturing clocks
- Any phase shifts applied when evaluating timing checks
- Any CPPR values applied to timing check evaluation

The `report_timing` command output accommodates both the instance pin names and net names in the same column. Since both instance pin names and net names can be long, to save screen space alternating instance pin and net names (depending on whether the row displays gate delay or net delay) are reported in a single column.

When the `timing_report_timing_header_detail_info` timing attribute is set to `extended`, the software generates timing reports with additional header information, that includes the following details:

- Analysis mode - best-case worst-case (BCWC) or on-chip variation (OCV)
- Active views (displayed only in MMMC mode)
- Clock re-convergence pessimism (CPPR)
- Latch slack mode
- Specified clock propagation value
- Delay calculation
- Specified delay calculation engine

When the `timing_report_group_based_mode` attribute is set to `true`, the paths are grouped by clock domain. In this mode, the `report_timing` command will have the following four types of groups:

- Clock gating group: This is an internal group that reports the clock gating check type paths.
- Asynchronous group: This is also an internal group that reports the asynchronous check type paths.
- Groups for all clocks in a design: These are internal groups that are classified on the basis of each reference clock. The paths belonging to each reference clock are reported separately under each clock name's group. These groups do not honor the clock gating/asynchronous check types. Suppose there are three clocks C1, C2, and C3 in a design, then three groups will be reported for each of these clocks. The endpoint sharing the same reference clock will be part of the same

group. In case the endpoint belongs to multiple groups then it will be reported separately in each group.

- Default group: This is an internal group that reports combinational maximum or minimum delay paths.
- User-defined groups: These are user-defined path groups that can be created by users with single or multiple constraints. These groups honor all the check types and are reported by default.

By default, the `timing_report_group_based_mode` attribute is set to `false`.

Note: This attribute does not honor user-defined path groups, so the paths will still be grouped by different clocks.

The `report_timing` command supports multi-threaded reporting. You can make the following settings to enable multi-threaded reporting:

```
set_multi_cpu_usage -localCpu number_of_CPU
```

```
set_table_style -no_frame_fix_width [-nosplit]
```

Note: When the `timing_allow_input_delay_on_clock_source` attribute is enabled and the `set_input_delay` command is applied to a clock input, the specified delay value will be considered as the source clock latency for clock paths and as regular data path arrival time for clock source paths.

You can use a one-step method for generating merged MMMC view reports from DMMMC master shell. After running the `distribute_views` command, you can use the `report_timing` command to generate reports collectively from all the active distributed views (that is, views available for interactive DMMMC analysis). The merged output report is arranged as per the slack/criticality order across active views.

When the `timing_enable_wire_variation` attribute is set to `true`, the timing reports show wire variation details in the below columns:

- `retime_slew_wire_stddev`
- `retime_delay_wire_stddev`
- `arrival_wire_stddev`

For more details on wire variation, refer to the "Wire Variation Analysis" chapter in the *Tempus Stylus User Guide*.

- [Related Information](#)

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>report_timing</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_timing.</code>
<code>{> >>} filename</code>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software will overwrite it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software will concatenate the report at the end of the file. The <code>filename</code> parameter must be the last argument in the list. The <code>filename</code> and <code>-tcl_list</code> parameters are mutually exclusive; you cannot specify them together. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. Note: The last argument specified with the <code>report_timing</code> command is not considered a filename. <i>Default:</i> Report is displayed on standard output (not saved).
<code>-analysis_summary_csv_extended_file string</code>	Generates the CSV file to be used for merging. <i>Data_type:</i> string, optional
<code>-analysis_summary_csv_file string</code>	Generates the analysis summary CSV file. <i>Data_type:</i> string, optional

<code>-analysis_summary_file <i>string</i></code>	Generates the analysis summary file. <i>Data_type</i>: string, optional
<code>-begin_end_pair</code>	Reports all the violating paths between unique source and target register pairs. To report other paths, you can specify this parameter with the <code>-max_slack</code> parameter. The paths are not sorted by slack - paths with the same source pins are reported adjacent to each other. When specified with the <code>-from</code>, <code>-through</code>, or <code>-to</code> parameter, the software only reports the unique register pair paths that match the path description. In merged group-based reporting mode (that is, when <code>timing_report_backward_compatible_max_paths_reporting</code> attribute is set to <code>false</code>), the <code>report_timing -begin_end_pair</code> command <code>report_timing -begin_end_pair</code> will always report the paths grouped by <code>path_groups</code> irrespective of <code>timing_report_group_based_mode</code> attribute setting. You can use the <code>timing_report_begin_end_pair_max_path_limit</code> attribute to specify the maximum paths limit. When the number of maximum paths to be reported by the <code>-begin_end_pair</code> parameter exceeds the specified limit (default is 200000), a warning message will be displayed. Also, some of the paths may not be reported. Note: You cannot specify this parameter with the <code>-max_paths</code>, <code>-nworst</code>, <code>-unique_pins</code>, and <code>-min_slack</code> parameters. <i>Data_type</i>: bool, optional

<code>-check_clocks</code>	Generates reports based on timing paths on the clock network instead of the standard timing to data endpoints. This report includes clock paths that end at the reference end of a check or a clock gating end point. <i>Default:</i> Data paths and all the other clock paths (for example, a clock path ending at a D pin of a register) are reported. <i>Data_type:</i> bool, optional
<code>-check_type check_type</code>	Reports only the paths that end at the specified timing check. You can specify the following options: setup, hold, clock_gating_setup, clock_gating_hold, clock_gating_pulse_width, data_setup, data_hold, recovery, removal, pulse_width, clock_period, clock_separation, skew, no_change_setup, no_change_hold, max_delay, and min_delay. • The clock style checks are: pulse_width, clock_gating_pulse_width, clock_period, skew, and clock_separation. • In setup analysis mode, the reported check types will be: setup, skew, pulse_width, clock_period, clock_gating_setup, clock_gating_pulse_width, data_setup, recovery, clock_separation, and no_change_setup. • In hold analysis mode, the reported check types will be: hold, clock_gating_hold, data_hold, removal, and no_change_hold. If the software is in simultaneous setup and hold analysis mode, all of the check types listed above will be reported. When the <code>max_delay</code> and <code>min_delay</code> options are specified, the timing report will display details of timing paths for which the <code>set_max_delay</code> or <code>set_min_delay</code> constraints are defined.

	By default, the following checks are reported: • setup • hold • clock_gating_setup • clock_gating_hold • data_setup • data_hold • recovery • removal • no_change_setup • no_change_hold Do not use this parameter with the <code>-unconstrained</code>, <code>-early</code>, or <code>-late</code> parameters. Note: The <code>report_timing</code> command does not perform skew checks by default. <i>Data_type</i>: enum, optional
<code>-collection</code>	Returns a collection of timing paths, which is useful for performing Tcl queries on selected timing reports. To generate a collection of paths analyzed by Path-Based Analysis (PBA), you can use the <code>-retime</code> parameter. Note: This parameter is not supported in DMMMC mode. <i>Data_type</i>: bool, optional

<pre>-debug {unconstrained time_borrow cpr_point constraint_arc context wire_variation vt_skew}</pre>	You can specify the following options for debugging: • unconstrained: Determines the reasons for a path to be unconstrained. The report output will list all the applicable arcs/constraints that could not constrain the paths, along with the reasons. • time_borrow: Reports time borrowing calculations. Time borrowing is the amount of time borrowed by a previous logic. • cpr_point: Reports the CPR point information for the reported paths. • constraint_arc: Reports check arc details, such as, constraint arc delay, constraint pins (along with the related pin slews), skewness, user derate, annotation, and when_cond. • context: Reports the launch and capture path interface timing for each instance and indicates the block port that shows latency in the MIM flow. • wire_variation: Reports the corresponding slack shift details at the end of each timing path report. • vt_skew: Reports voltage threshold (VT) skew analysis details. <i>Data_type:</i> string, optional
<pre>-derate_summary</pre>	Generates a summary table for AOCV derating of launch and capture paths. <i>Data_type:</i> bool, optional
<pre>-fields column_list</pre>	Formats the report according to the specified <i>column_list</i>. The <i>column_list</i> specifies the columns to be displayed in the timing report and the order in which they appear. The valid field columns are: adjustment, abs_delay_err, abs_transition_err, annotation, aocv_adj_stages, aocv_derate, aocv_weight, arc, arrival, arrival_mean, arrival_sigma, cell, delay, delay_mean,

delay_sigma, direction, edge, fanin, fanout, flags, hpin, incr_delay, instance, instance_location, latch_window, load, module, net, pct_delay_err, pct_slew_err, phase, phys_info, pin, pin_load, pin_location, power_domain, required, retime_delay, retime_delay_mean, retime_delay_sigma, retime_mis_delta, retime_mis_derate, retime_slew, retime_transition_mean, retime_transition_sigma, stage_count, transition, transition_mean, transition_sigma, socv_derate, spice_arrival, spice_delay, spice_slew, stolen, timing_point, total_derate, user_derate, voltage, vt_skew_derate, when_cond, wire_load, wmodel

For example:

```
-fields {hpin cell delay required arrival  
required edge}
```

See [Report Timing Column List](#) for details on the above options.

Few notes:

- The default net format (with the `-net` parameter) for the full path will be:

```
{hpin edge net cell delay arrival required}
```
- The `required` column will not be displayed, when the `-unconstrained` parameter is specified.
- The `adjustment` column is automatically added to the timing report. To disable this feature you can set the `timing_report_generated_clock_info` attribute to `false`. By default this global variable is set to `true`.
- You can use a combination of the `-fields` and `-tcl_list` parameters to integrate the timing reports into your Tcl scripts. You can use the `-from` parameter to limit the number of paths reported, and to find specific paths in the design.
- The `-format` option cannot be used with the `-path_type summary` option.
- You can manage the retiming columns with

	the <code>timing_report_retime_formatting_mode</code> global variable. - If you specify the <code>report_timing -split_delay</code> parameter, then the timing report format will change to: <pre>{timing_point flags edge cell power_domain fanout transition delay arrival}</pre> - Informational tags are displayed for reporting additional details with the <code>flags</code> option. For details on the 'Flags' column, refer to the section on Use of Informational Flags. Default: <code>{timing_point flags arc edge cell power_domain fanout transition delay arrival}</code>
<code>-from -from_rise -from_fall</code> <code>object_list</code>	Reports paths starting from the object(s) specified in the <code>object_list</code>. The supported objects are pins, ports, and clocks. Using <code>-from_rise</code> (or <code>-from_fall</code>) parameter specifies that the rising (or falling) edge of the signals on the objects in the <code>object_list</code> are the start of the paths. This parameter also reports on source clock waveform(s). You can use this parameter with the <code>-through</code> and <code>-to</code> parameters for specifying particular paths in the design. Data_type: string, optional
<code>-group groupname_list</code>	Reports paths contained in the groups specified in the <code>groupname_list</code>. Data_type: string, optional
<code>-gui</code>	Displays the timing report in a GUI window. Data_type: bool, optional
<code>-hpin</code>	Prints all the hierarchical crossings of an arc under the <code>hpin</code> column. Data_type: bool, optional

<code>-late -early</code>	Reports for early paths (hold checks) or late paths (setup checks). If you specify a check type, setup or hold, with the <code>timing_analysis_check_type</code> attribute, the <code>report_timing</code> command reports the specified check by default. Note: The <code>-early</code> and <code>-late</code> parameters are not mutually exclusive; you can specify them together. <i>Default:</i> <code>-late</code> <i>Data_type:</i> bool, optional
<code>-max_delay float</code>	Specifies the path delay limit for unconstrained paths. <i>Data_type:</i> string, optional
<code>-max_paths integer</code>	Reports the specified number of worst paths in the design, with maximum of <code>nworst</code> (<code>-nworst</code> parameter) paths to any single endpoint (default 1). When <code>timing_report_group_based_mode</code> (group-based mode) attribute is set to <code>true</code>, the <code>-max_paths</code> parameter specifies the number of worst paths reported per clock group. <i>Default:</i> 1 <i>Data_type:</i> int, optional
<code>-max_slack float</code>	Reports only those paths with slack less than the specified maximum slack value. The <code>-max_slack</code> parameter reports paths that fall within the specified range. A positive slack value indicates that timing was met and a negative slack value indicates a timing violation. When the <code>-retime_mode exhaustive</code> option is specified, the <code>-max_slack</code> value is set to 0. The <code>-max_slack</code> parameter cannot be used with the <code>-unconstrained</code> option. <i>Data_type:</i> string, optional
<code>-min_slack float</code>	Reports only those paths whose slack is greater

than the specified minimum slack value.

You can generate a timing report showing paths with slack greater than the specified slack using the `-max_paths` parameter. For example, to report all paths with slack greater than 2ns, you can use the following command:

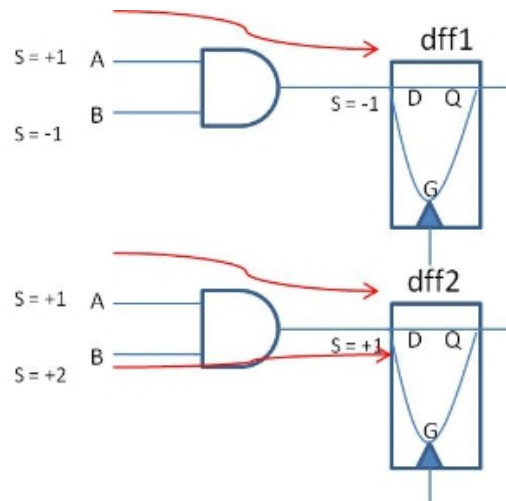

```
min_slack 2.0 -max_paths 1000
```

In this case the maximum number of paths reported will be 1000.

When the `-min_slack` parameter is specified, the total numbers of paths processed will be as determined by the `-max_paths/-nworst` settings and only those paths satisfying the `-min_slack` criteria will be reported. The software will not process paths beyond the specified `max_paths/nworst` limit, even if the `min_slack` criteria is satisfied.

The `-min_slack` cannot be used with the `-unconstrained` parameter.

In the below diagram, if `-min_slack` is 0 and `-max_paths 4 -nworst 2` is specified, then only 3 paths will be reported; path with slack value of -1 will be ignored. Here, even if there is another path with slack that is greater than or equal to 2, then it will not be reported because worst `max_paths` have been processed.

Data_type: string, optional

<pre>-nets</pre>	Adds a row to the "Timing Point" field column to display the net names. Note: The <code>-split_delay</code> and <code>-nets</code> parameters can be used together. <i>Data_type:</i> bool, optional
<pre>{-not_through -not_rise_through -not_fall_through} object_list</pre>	You can specify one of the following options: • <code>-not_through</code>: Reports paths that do not traverse through the specified nets, ports, or pins of a cell. By default, this parameter will be ignored if an object has already been specified. In this case the parameter shows the following behavior: ◦ If a collection of all the input ports has been specified (using the <code>all_inputs</code> command), then the report will show paths to the inout part, and paths starting from the internal part of inout will be excluded. ◦ If a collection of all the output ports has been specified (using the <code>all_outputs</code> command), then the report will show paths starting from the internal part of inout, and paths ending at inout part will be excluded. ◦ If any other collection (not specified with <code>all_inputs</code> or <code>all_outputs</code> command) is specified, then paths to both the ports will not be reported. • <code>-not_rise_through</code>: Does not report paths with rise transition. • <code>-not_fall_through</code>: Does not report paths with fall transition. <i>Data_type:</i> string, optional

<code>-nworst <i>integer</i></code>	Specifies the maximum number of paths which can be reported for a particular endpoint (the total number of paths reported is specified by the <code>-max_paths</code> parameter). When <code>timing_report_group_based_mode</code> attribute is set to <code>true</code> (group-based mode), the <code>-nworst</code> parameter specifies the maximum number of paths for a particular endpoint per clock group. You can use the <code>-nworst</code> parameter to report all the checks at an endpoint (or use <code>-check_type</code>) to report a specific check. Default: 1 <i>Data_type</i>: int, optional
<code>-output_format {text csv gtd binary}</code>	Generates a detailed timing report in the specified format - text, CSV, GTD, or binary. <i>Data_type</i>: enum, optional

```
-path_exceptions {applied | ignored |  
all}
```

Includes information of path exceptions applied and considered for the reported path. You can specify the following options:

- **applied:** Reports the honored exception on the reported path.
- **ignored:** Reports the ignored exceptions on the reported path.
- **all:** Reports both applied and ignored set of exceptions on the reported.

Note: Analyzing all the exceptions for a path will cause increase in runtime.

If multiple from, to, or through pins are specified, the exception report for that path will show only those pins that are part of the current path.

Note: If a path is already unconstrained, then all further path exceptions applied on that particular path will be reported as ignored exceptions.

The `-path_exceptions` parameter also reports `-start/-end` options with multi-cycle paths. Without the start or end specification, by default, the setup check is relative to the end clock and the hold check is relative to the start clock. The `report_timing -path_exceptions all` command will report all the non-default `-start/-end` specifications.

You cannot use this parameter with the following parameters:

- `-point_to_point`
- `-collection`
- `-path_type`
- `-tcl_list`

Also, you cannot use this parameter with block-based SSTA.

Note: Analyzing all the exceptions for a path will increase the runtime.

Data_type: enum, optional

```
-path_type {endpoint | summary | full |  
full_clock}
```

The `-path_type` parameter allows you to choose the report format by path type.

You can specify one of the following options:

- `endpoint`: Generates an endpoint report for each path containing the ID, slack, endpoint, and group view. This option generates a very fast report.
- `summary`: Generates a summary report for each path consisting of a start point, endpoint, cause, slack, arrival time, required time, and phase. The `-fields` option does not have any impact on this report format.
- `full`: Generates a report that displays the full path with accompanying required time and slack calculation. This is the default path type. You can control the report format using the `-fields` option.
- `full_clock`: If the reported path ends at a timing check, the software reports the full clock path (Other End Path), in addition to the full data path (Timing Path).

Data_type: enum, optional

`-point_to_point`

Traces the worst delay path between a pair of from-to pins. The paths reported with this parameter only include the cumulative delay of the path. You must specify either the `-from` or `-to` parameter, to define the begin and end points of the path.

If you do not specify a `-from` pin, the standard definition of the begin point of a path applies. If you specify a `-from` pin, it is treated as the begin point of the path. If you specify a `-from` pin that is not a valid begin point, the arrival time of the first pin starts from 0.

If you do not specify a `-to` pin, the standard definition of the end point applies. If you specify a `-to` pin, it is treated as the end point, and only those paths ending in `-to` pins are reported. If you specify more than one `-to` pin, the worst path to each pin-to-pin is reported.

When from-to pins are specified, the software will trace across the trigger arcs and report a path, if there is a clock reaching the CK pin of the trigger arc. However, if there is a begin or end point present between the `-from` and `-to` pins, the software will not trace beyond it.

If there is no clock reaching the CK pin of the trigger arc, the software cannot trace across the trigger arc, and no path is reported. Additionally, clock path delay is included only when the clock is in propagated mode.

Note: The `-point_to_point` and `-through` parameters are mutually exclusive; you cannot specify them together.

Note: The `-point_to_point` parameter supports a single `-from` and `-to` pin; a list of pins is not supported.

Data_type: bool, optional

<pre>-retime_delaycal_pins pin_name</pre>	Reports the PBA delay calculation details for timing arcs that fanin to the user-specified to-pin list. You can specify multiple pins in the pin list. The delay calculation report will be printed at the end of each timing path for the arcs, which are retimed in that path. The PBA delay calculation report format is similar to the report_delay_calculation output in GBA mode, however, the results may vary because this output is based on path-based analysis. When a cell output pin list is provided, the generated report is for the cell arcs; the cell input pin list generates the net arc report. This parameter is supported for PBA reporting only. <i>Data_type</i>: string, optional
<pre>-retime_format {manual retime_compare retime_replace}</pre>	Allows you to set the format of timing reports for retime related fields. You can specify one of the following options: • manual: Does not change the report_timing format. • retime_compare: If GBA columns are present in the report format, then the corresponding retime options are added. If PBA columns are already present, then there is no change in the format. • retime_replace: If GBA columns are present in the report format, then the GBA columns are replaced by the corresponding PBA columns. If PBA columns are already in the report, then there is no change in the format. Note: The timing report format can be controlled with the timing_report_retime_formatting_mode attribute. The report_timing command setting has precedence over this attribute. <i>Data_type</i>: enum, optional

<pre>-retime_mode {path exhaustive}</pre>	Reanalyzes the specified set of paths using the specified method. You can use one of the following options: • path: Reanalyzes the specified set of paths. By default, the software uses the <code>-retime_mode path</code> setting, when the <code>-retime path_slew_propagation</code> option is specified. • exhaustive: Enables exhaustive path-based analysis mode. In this mode, the software will exhaustively examine <code>nworst</code> paths of the selected endpoints and then select the true worst path to be reported, based on retimed slacks of all the examined paths. When you use this option, reporting can be runtime intensive as the software needs to run an exhaustive search for true worst paths. Therefore, it is recommended to use this option in the later phases of the signoff stage when few violations are left for analysis. <i>Default:</i> <code>path</code> <i>Data_type:</i> enum, optional
<pre>-retime {aocv path_slew_propagation aocv_path_slew_propagation}</pre>	Reanalyzes the specified set of paths using path-based analysis (1 path per endpoint). Note: This feature is not meant to be run on all the paths of a design. You can specify the following options: • aocv: Computes AOCV stage count based on specific paths and applies the AOCV derate values to GBA (graph-based analysis) delays. This option can be used with the following parameters only: ◦ <code>-rise/-fall</code> ◦ <code>-early/-late</code> ◦ <code>-check_type</code> ◦ <code>-max_paths</code>

- `-begin_end_pair`
- `-from/-from_rise/-from_fall`
- `-through/-through_rise/ -through_fall`
- `-to/-to_rise/-to_fall`
- `-rise/-fall`
- `-early/-late`
- `-check_type`
- `-max_paths`
- `-begin_end_pair`
- `-from/-from_rise/-from_fall`
- `-through/-through_rise/ -through_fall`
- `-to/-to_rise/-to_fall`
- `-path_exceptions`
- `-path_type`
- `-max_slack`
- `-min_slack`
- `-view`
- `-derate_summary`
- `-nworst`
- **path_slew_propagation:** Re-evaluates the given set of graph-based analysis (GBA) paths by recalculating the delay values based upon actual propagated slew across the path. In this case the AOCV derates are the ones that are reported during graph-based analysis.

The default timing analysis uses worst-case slew propagation to calculate the delays at each stage. As a result, the timing analysis results can be pessimistic.

Note: This feature should be run only on paths that do not meet the slack margin criteria to help identify the actual failing paths from those that are simply

failing due to the conservative delay calculation.

The signal integrity incremental delays can be recomputed for the entire path. You can use the following command to perform path-based signal integrity analysis:

```
report_timing -retime path_slew_propagation
```

In the `report_timing` command output, the `Retime Incr Delay` column reports recomputed signal integrity delays.

The `-retime` parameter also supports retiming a collection of paths. This parameter does not retime an already retimed path collection. This feature works in graph-based analysis (GBA) mode for path collections. You can use the following use model to retime collections:

```
report_timing $collection -retime  
path_slew_propagation
```

A path collection stores context dependent data, that is, a delay property in GBA will reflect delay data of the timing path report generated in GBA mode. The same property in PBA will reflect the retime delay data of the timing path report in PBA mode.

The delay column in timing reports is context dependent, when the

```
timing_report_retime_formatting_mode  
retime_replace
```

 attribute is used.

Note: For memory optimization purposes, both the delays will not be stored in the same path collection. You can use this setting for comparison purposes.

- `aocv_path_slew_propagation`: Re-evaluates the given set of graph-based analysis (GBA) paths by using path-based AOCV derates and delays using actual path-based propagated slew. This option is a combination of `-aocv` and `-path_slew_propagation` options.

For retime report header details, see [Retime Analysis Report Header Flags](#).

Data type: enum optional

<code>-skip_io_paths</code>	Specifies whether the input/output paths are to be ignored. <i>Data_type</i>: bool, optional
<code>-rise -fall</code>	Reports the path with the specified edge on the endpoint. If an endpoint is specified using the <code>-to_rise</code> (or <code>-to_fall</code>) parameter, the <code>-rise</code> (or <code>-fall</code>) parameter is ignored and paths with edge specified by <code>-to_rise</code> (or <code>-to_fall</code>) are reported. The <code>-rise</code> option applies to endpoints only. <i>Data_type</i>: bool, optional
<code>-split_delay</code>	Adds a row for the net arc. Note: The <code>-split_delay</code> and <code>-nets</code> parameters can be used together. <i>Data_type</i>: bool, optional
<code>-tcl_list</code>	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions and also for customizing report generation. The <code>-tcl_list</code> and <code>filename</code> parameters are mutually exclusive; you cannot specify them together. <i>Data_type</i>: bool, optional

<pre>-through -through_rise -through_fall <i>object_list</i></pre>	Reports paths that pass through pin(s) or net(s) specified by the <i>object_list</i>. Any number of <code>-through</code> pins or nets can be specified. Using the <code>-through_rise</code> (or <code>-through_fall</code>) parameters specifies that the paths go through the rising (or falling) edge of the signals on the pins/nets in the <i>object_list</i>. The <i>object_list</i> is a logical OR function. The resulting path may pass through any of the pins or nets in the <code>-through <i>object_list</i></code>. To force the report to pass through multiple pins or nets, separate <code>-through</code> statements are needed. You can use these parameters with the <code>-net</code> parameter. <i>Data_type</i>: string, optional
<pre>-to -to_rise -to_fall <i>object_list</i></pre>	Reports paths leading to the pin(s) specified by the <i>object_list</i>. The pins in the <i>object_list</i> can be either pins on the design boundary (ports) or pins on an instance. Only one list of <code>-to</code> pins can be specified per report. Using <code>-to_rise</code> (or <code>-to_fall</code>) specifies that the rising (or falling) edge of the signals on the pins in <i>object_list</i> are at the end of the paths. This parameter also reports on target clock waveform(s). The <code>-to_rise</code> option applies to endpoints as well as intermediate pins. <i>Data_type</i>: string, optional

<code>-unconstrained</code>	Reports only the unconstrained paths (paths with no slack). Each signal arriving at the path end node which does not have a matching required time, results in an unconstrained path. The <code>report_timing</code> command without the <code>-unconstrained</code> parameter reports only constrained paths. If no constrained path is found, there may be unconstrained paths or paths may not exist. Note: The <code>-min_slack</code> and <code>-max_slack</code> cannot be specified with the <code>-unconstrained</code> parameter. See Examples for the conditions under which a path is reported as constrained or unconstrained. <i>Data_type:</i> bool, optional
<code>-unique_pins</code>	Reports paths that pass through unique set of pins. When this parameter is specified, in group-based mode for a given begin-end point pair, the software will consider all different launch clock paths for reporting unique paths. If for a given begin-end pair and a given capture clock, there is a possibility of different launch clock paths, then each such path will be reported. Note: Using this parameter may significantly affect runtime and memory usage, if the number of reported paths is high.

`-view viewName`

Generates report for the specified analysis view. By default, all the active views are analyzed.

You must be in multi-mode multi-corner (MMMC) analysis mode in order to use this parameter. To create a view, you use the `create_analysis_view` command. To set an active view for analysis, you use the `set_analysis_view` command.

The `report_timing` command performs block-based analysis in MMMC mode. By default, the command reports the worst endpoint(s) across all views. You can use the `-view` parameter to report for individual views.

Default: Reports the worst path to each endpoint across all the analysis views.

Data_type: bool, optional

Group Path Reporting for User-Defined Groups

- A user-defined group is created with the same name as any of the defined reference clocks and with the same constraint as for the "to" clock. For example, `group_path -name CLK -to CLK`. In this case only one group named `CLK` will be displayed in the timing report. This will be the same default group with reference clock `CLK`. Note that default groups - clock gating and asynchronous checks - will not be honored for this group.
- A user-defined group is created with the same name as any of the reference clocks but with different constraint as specified for the "to" clock. E.g., `group_path -name CLK -from pin1 -to CLK`. In this case the two groups named `CLK` will be displayed in the timing report. One group will be the same as the default group with reference clock `CLK` (which will not honor clock gating or asynchronous checks) and the other will be the user-defined path group with name `CLK`, which will honor all the checks.

Use of Informational Flags

Informational tags are used providing additional details. The following informational tags are supported:

Flags	Description
(i)	Net is ideal
(P)	Instance is preserved / don't_touch
(p)	Instance is preserved / don't_touch but may be resized

The output format uses the flag keys on the timing report and adds a description at the end of the report for reference. A sample output is as shown below:

```
#-----
# Timing Point   Delay (ns) Latch   Window   Arrival   Arc   Flags   Adjustment
# (ns)
#-----
f0/CP            -           -       1.000000           CP       -       -
f0/Q             0.254100   -       1.254100           CP->Q    -       -
b32/Z            0.598446   -       1.852546           I->Z     -       -
...
b4/Z             0.086940   -       2.502181           I->Z     -       -
f1/D             0.000000   -       2.502181           D        <<<    -
#-----
```

```
(P) : Instance is preserved
(p) : Instance is preserved but may be resized
(i) : Net is ideal.
(b) : Timing paths are broken.
```

Retime Analysis Report Header Flags

AOCV(default)	Indicates that the selected retime analysis includes recalculation of path depths and AOCV derates. The AOCV retime is enabled with the <code>-retime aocv</code> or <code>aocv_path_slew_propagation</code> parameter. The AOCV stage counting mode (specified using the <code>timing_aocv_analysis_mode</code> attribute) is indicated in parenthesis. The stage counting modes are given below: ● <code>launch_capture</code> (default) (Default) ● <code>combine_launch_capture</code> (Combine) ● <code>separate_clock_data</code> (Separate) ● <code>clock_only</code> (Clock)
Corr	Indicates that the current SOCV accuracy mode considers correlation of variation between stages. Starting with SOCV accuracy mode <code>medium</code> (specified with the <code>delaycal_socv_accuracy_mode</code> attribute), it is assumed that some portion of the variation is not completely uncorrelated random variation, so the software tracks a correlated and uncorrelated component for each of the applicable moments.
Data Clock	Indicates the portion of the path that has been retimed. By default, only the data path is retimed. If the <code>timing_disable_retime_clock_path_slew_propagation</code> attribute is set to <code>false</code>, then the clock path will also be retimed, and “Clock” will be added to the retime status.
EWM	Indicates that equivalent waveform model is used (<code>delaycal_equivalent_waveform_model</code> attribute).
GBA COLL	Shows a collection of paths for which retime analysis is not performed. This can be controlled with the <code>When</code> the <code>report_timing -path_type exhaustive -collection</code> command. By default, the <code>report_timing -collection</code> parameter does not show GBA and PBA slack values separately.

GP	Indicates that graph-based PBA mode settings are enabled.
GS	Indicates that GBA skewness mode settings are enabled.
PBA COLL	Shows a collection of paths for which retiming analysis is performed while creating the collection. This can be controlled with the <code>When</code> the <code>report_timing -path_type exhaustive -collection</code> command. By default, the <code>report_timing -collection</code> parameter does not show GBA and PBA slack values separately.
Path-Slew	Indicates the selected retiming analysis is set to use path correct slew rates to reduce the pessimism from slew merging. This can be controlled with the <code>report_timing -retiming</code> parameter. The path slews are recalculated in <code>path_slew_propagation</code> and <code>aocv_path_slew_propagation</code> modes.
PG	Indicates that group-based mode reporting is enabled when N paths are reported for every group.
RC	Indicates that RC variation is enabled with the <code>timing_socv_rc_variation_mode</code> attribute setting, and a SOCV format RC variation side file library is available.
SI	Indicates that SI analysis was enabled during retiming analysis. The path-based analysis will recompute SI effects using path correct victim timing windows.

SOCV(Ultra)	Indicates that SOCV analysis is enabled and has been incorporated into the retiming. The SOCV analysis mode (specified with the <code>delaycal_socv_accuracy_mode</code> attribute) is shown in parenthesis. The accuracy modes are mapped as follows: • low <not shown> • medium Medium • high High • ultra Ultra
Spatial (CS)	Indicates that spatial derating side files have been loaded and an explicit spatial derate factor will be calculated. This is not shown for AOCV 2D derate tables, where the spatial and depth derates are combined. The GBA spatial derate mode (specified with the <code>timing_spatial_derate_distance_mode</code> attribute) is shown in parenthesis with the possible values given below: • chip_size (CS) • arc_bounding_box (ARC) The GBA spatial derate mode does not affect the path-based analysis bounding box calculation.
WP	Indicates that waveform propagation is enabled (using the <code>the delaycal_equivalent_waveform_model</code> attribute). The path-based retime will also use this delay calculation accuracy setting when recomputing delays and transitions for the path.

Examples of GBA/PBA Collection Reports

- When the `report_timing -path_type exhaustive -collection` command is specified, the following command generates a GBA collection report as shown below:

```
tempus > report_timing $tim_coll ; set tim_coll [report_timing -path_type exhaustive -collection]
```

```
**WARN: (TCLCMD-1248): Since no '-max_slack' has been specified with exhaustive '-
retime_mode', tool will assume it's default value in this case which is '0'
**WARN: (TCLCMD-1251): The PBA exhaustive mode '-nworst' limit has been exhausted for
some of the endpoints. Refer to verbose log file of current session for more details.
INFO: Path Based Analysis (PBA) performed on total '3' paths
INFO: Max depth 3 reached for end point 'htb/CG_REBAL_HIER_IN21/RC_IC_IN_1/E' during
Path Based Analysis
```

```
Path 1: VIOLATED Clock Gating Setup Check with Pin htb/CG_REBAL_HIER_IN21/RC_IC_IN_1/CK

VT Skew Reports

The following informational tags are supported for VT skew reports:

Flags	Description	Command Settings
VT-Skew	Shows VT skew details.	set timing_enable_vtskew_derate_mode true
PBA	Shows that the current path has undergone VT skew analysis. However, all the paths might not be considered VT skew candidates - even if VT skew analysis mode is enabled.	set_vt_skew_config - unique_vt_mode {none slow fast nominal}
PU	Indicates unique VT skew for PBA. Displayed when unique VT mode is enabled.	set_vt_skew_config - unique_vt_mode {slow fast nominal}
GU	Indicates unique VT skew for GBA. Displayed when unique VT mode is enabled.	

A sample report is shown below:

```
Path 1: MET Hold Check with Pin CRE_IN/EXE_IN/top_reg[11]/CP

Report Timing Column List

Option	Description
adjustment	Reports generated clock adjustment values. When reporting the detailed path for a generated clock, there are circumstances where the arrival time needs to be adjusted when a <code>create_generated_clock</code> assertion is encountered along the path. The adjustment argument can be used to provide a clearer indication of why a "jump" in the arrival time is seen in the path report. There are two primary reasons for generated clock-related adjustment to occur. • If the <code>timing_enable_generated_clock_edge_based_source_latency</code> attribute is set to <code>false</code>, it is possible that the edge-to-edge requirement specified by the generated clock cannot be satisfied by an existing logic path. This can happen when the source clock to generated clock polarity of the constraint is non-inverting, but the clock path itself constrains an inverting path. In this case, it would be normal to see a half-cycle of adjustment as the software compensates for the path versus constraint mismatch. If the above mentioned attribute is set to <code>true</code>, the software handles the path versus constraint mismatch by zeroing the source latency of the generated clock, and forcing alignment of the source and generated clock. As a result, no further adjustment is required, or reported. • In cases where <code>create_generated_clock -edge_shift</code> is specified, the adjustment column will show the amount of shift specified.

abs_delay_err	Reports the absolute delay difference of Tempus from Spice.
abs_transition_err	Reports the absolute slew difference of Tempus from Spice.
annotation	Reports RC parasitic annotations for net arcs, and delay annotations for either gate or net arcs. The following annotations are reported: • SDF: SDF back-annotation. The annotation status reflects the gate arc, not the interconnect arc. • SPEF: This entry appears if parasitic extraction has been done or annotated using SPEF. • LumpedRC: Lumped RC annotation • DlyAssert: Assertion set with set_annotated_delay command • WLM: Wire load model back-annotation • <none>: All others
aocv_adj_stages	Shows up "Aocv Adjust Stages" column. This column reports the AOCV adjustment stages that indicate the total effective stage count.
aocv_derate	Reports the graph-based AOCV derating factor used for cells/nets in AOCV mode. In retime mode, this column will report graph-based derating for cells/nets before the AOCV branch point and path-based derating.
aocv_weight	Reports AOCV weight values for the path elements.
arc	Reports the arc as described by the from pin, from pin edge, to pin, and to pin edge. For example, the arc from the rising edge of pin A to the falling edge of pin Z is reported as A -> Z.
arrival	Reports the arrival time on the pin.
arrival_mean	Reports mean of the arrival time on a pin.
arrival_sigma	Reports standard deviation of the arrival time on a pin.

cell	Reports the cell name of the given pin's instance.
delay	Reports the arc delay. If the stolen slack at the arc output pin (output of transparent latches) is not zero, the stolen column is also displayed along with this column.
delay_mean	Reports the mean of each arc's delay.
delay_sigma	Reports the standard deviation of each arc's delay. Note: In the absence of correlated and uncorrelated components of variation, the individual delay sigma values will not be summed up.
direction	Reports the pin direction (IN, OUT).
edge	Reports the edge of a pin (^=R, v=F).
fanin	Reports the number of source nodes of a net connected to a timing pin.
fanout	Reports the number of sinks of a net connected to a timing pin.
flags	Indicates the size_only, dont_use, dont_touch, and ideal attributes. When the 'flags' option is specified, a capacitance group entry (if it exists) will be displayed under the "Flags" column. This value indicates the input capacitance group being used for delay calculations – C1C2 (2-piece model) or C1CN (n-piece model).
hpin	Reports the hierarchical name for a given pin. Note: The hpin, pin, and timing_point will print the same values in the report output.
incr_delay	Reports the incremental delay of a pertaining arc. The software reads the incremental delay from an incremental SDF file using the read_sdf command.
instance	Reports the hierarchical name of a given pin's instance.

instance_location	Reports the location (x,y) of an instance. If a design is not placed, this column will be blank. This option displays the <code>instance</code> column automatically.
latch_window	Reports the available window for latch to sample the data.
load	Reports the total capacitance load on a given pin.
module	Reports the module name of the corresponding block hierarchy. This hierarchical module name will be reported only when the <code>-hpin</code> parameter of the <code>report_timing</code> command is specified.
net	Reports the hierarchical name of a net connected to a given pin.
pct_delay_err	Reports the percent delay difference of Tempus from Spice.
pct_slew_err	Reports the percent slew difference of Tempus from Spice.
phase	Reports the phase name of a pin.
phys_info	Shows minimum/maximum assigned layer, and non-default rule name information.
pin	Reports the reference name for the given pin.
pin_load	Reports the pin load data. The pin load refers to the sum of pin capacitance of all the pins connected to the current net.
pin_location	Reports the location (x,y) of a pin. If a design is not placed, this column will be blank.
power_domain	Reports power domain details of the specified path instance.
required	Reports the required time on a pin.
retime_delay	Reports the recalculated arc delay based on the path being reanalyzed with the specified retime method.

retime_delay_mean	Reports the mean of the recalculated arc delay on the path being reanalyzed with the specified retime method.
retime_mis_delta	Reports MIS delta delay in PBA mode for MIS-aware timing arcs in the path.
retime_mis_derate	Reports MIS derate values (in PBA mode), when derate-based advanced multi-input switching (AMIS-Derate) analysis is enabled.
retime_delay_sigma	Reports the standard deviation of each parameter of an arc's retimed delay.
retime_slew	Reports the recalculated slew based on the path being reanalyzed with the specified retime method.
retime_slew_mean	Reports the mean of each parameter of an arc sink pin's retimed slew.
retime_slew_sigma	Reports the standard deviation of each parameter of an arc sink pin's retimed slew.
stage_count	Displays the aggregate stage count of a specific instance in graph-based analysis (GBA) mode, and the actual stage count in path-based analysis (PBA) mode.
transition	Reports the propagated slew at the given pin.
transition_mean	Reports mean of each parameter of an arc sink pin's slew.
transition_sigma	Reports the standard deviation of each parameter of an arc sink pin's slew.
socv_derate	Reports the SOCV or the spatial derating factor applied on the cells or nets in SOCV analysis mode.
spice_arrival	Reports the Spice arrival time at the timing point.
spice_delay	Reports the Spice delay of a timing arc.
spice_slew	Reports the Spice slew of a timing point.

stolen	Reports the slack stolen (or the time given to the previous stage) at the given pin. If the slack is not zero and the <code>delay</code> column is specified, then this column is displayed by default (but only visible on the output of transparent latches).
timing_point	Reports the hierarchical names for the given points.
total_derate	Reports the total derating factor applied on the corresponding cell or nets that reflect the combined impact of all the derates (OCV/AOCV/spatial) applied on each stage of the timing path. Note: By default, the software will take into account the negative delays and keep the SOCV derate column in sync with the user-derate column. The software multiplies the negative delay by (2.0 - derating factor) to make it more pessimistic. However, reporting will always show derates based on the positive delay. The timing report output will show similar values for the SOCV Derate and Total Derate columns, but there will be no changes in the slack values.
user_derate	Reports the derating scale factors set with the <code>set_timing_derate</code> command. Note: The timing system cannot provide an accurate derating factor for the lumped gate and wire delay when the <code>set_timing_derate</code> factors for <code>-cell_delay</code> and <code>-net_delay</code> are not equivalent. In this case, an asterisk (*) is reported in the SSI Derate column.
voltage	Returns the voltage that is used during delay calculations.
vt_skew_derate	Returns voltage threshold (VT) skew analysis details.
when_cond	Reports the "when" condition of the arc specified in the library.
wire_load	Reports the wire load.

wlmodel	Reports the kind of parasitic used by a pin or net, such as SPEF. If the wire load model is derived from a Liberty file, the information is reported in the following format: <pre>Wireload model (.lib model_name library_name)</pre>
---------	---

Reporting Timing Checks Between Various Types of Clocks

The following table summarizes the timing checks and the min/max delay checks that are performed based on the types of launching and capturing clocks:

- NZ (Non Zero Period Clock - Regular Clock)
- Z (Zero Period Clock - Regular clock whose period is equal to zero)
- @ (Asynchronous Clock - Clock which triggers the default input delay and the input delay without a clock)
- CPD (Combinational Path Delay)

Launching Clock	Capturing Clock	Timing Checks	Path Delay Checks
@	@	NO	CPD
Z	@	NO	CPD
NZ	@	NO	CPD
@	Z	YES	SPD
@	NZ	YES	SPD
NZ	Z	NO	SPD
Z	NZ	YES	SPD
Z	Z	YES	SPD
NZ	NZ	YES	SPD

Reports Sections

Path Summary Report

```
tempus > report_timing -path_type summary
```

A sample path summary report is shown below:

```
Path 1: VIOLATED (-16.913 ns) Setup Check with Pin CRE_IN/EXE_IN/p_reg[30]/CK->D

#-----							

By default, the timing reports show the 'path summary' and 'path description' section. However, the default can be changed by using the `report_timing -path_type` parameter.

Endpoint Reports

In addition to detailed reports, endpoint reports can also be generated. These reports allow you to include additional endpoint related information that can be useful in debugging or identifying certain issues. For example, an endpoint report can show the number of buffers and inverters on a path. A sample report is as shown:

```
tempus > report_timing -path_type endpoint
#-----
# ID      Slack      Endpoint              Group  View
#      (ns)
#-----
#      1      -16.913  CRE_IN/p_rg[30]/D  m_clk  def_em_view1
#-----
```

The endpoint reports and detailed reports are mutually exclusive.

Clock Tracing Reports

Optionally, the report includes the clock tracing section that helps in debugging issues pertaining to clocks used by the startpoint and/or endpoint of a path. Clock tracing traces the source of the clock and the detailed path taken to reach the launch and/or capture elements' clock pin. A sample report is shown below.

```
> report_timing -view func1@wc_cworst -path_type full_clock
    -from ff1_reg -to ff3_reg
```

```

        -fields {-fanout}
Path 1: MET (405 ps) Setup Check with Pin ff3_reg/CK->D
        View: func1@wc_cworst

- The `report_timing` command accepts `-collection` as an argument. For example,

```
report_timing [report_timing -collection]
set rpt [report_timing -collection]
report_timing $rpt
```
- The following command displays the worst late path to each violating endpoint that has a slack less than -1.0:

```
report_timing -max_slack -1.0
```
- The following command displays all the late paths that end at port `out[2]` and that have negative slack up to a maximum of 1000 worst paths. If there are more than 1000 paths, only the 1000 worst paths are reported:

```
report_timing -to out[2] -max_paths 1000 -max_slack 0.0
```
- The following command reports the worst late path that starts at `in[0]` and ends at `out[1]`:

```
report_timing -from in[0] -to out[1]
```
- The following command displays the three worst paths that start at `in[1]` and end at `out[3]`. With reconvergent fanout, more than one path may exist:

```
report_timing -from in[1] -to out[3] -max_paths 3
```

- The following command displays the ten worst paths. Only the paths between the specified pins are enumerated. With reconvergent fanout, more than one path may exist:

```
report_timing -from i102/Z -to i123/A -max_paths 10
```

- The following command enumerates the worst ten paths through the given two pins, starting at the beginning points in the design and ending at the endpoints, similar to using the `-from` option:

```
report_timing -through i102/Z -through i123/A -max_paths 10
```

- The following command reports the ten worst paths through blocks A and C, or blocks B and C. The path only has to satisfy one element in a through list, but all through lists must be satisfied. The example can be thought of as ((A or B) and C):

```
report_timing -through {A/*B/*} -through {C/*} -max_paths 10
```

- The following command forces a path through pin A and pin B. Use the syntax shown in the example. Do not use `-through {A B}`:

```
report_timing -through A -through B
```

- The following command displays the clock path through the clock root to Launch flop:

```
report_timing -through aBC_bs/bs_mex1/r2_00_q1_reg_10_/CK -to .... -path_type full_clock
```

- You will not see the path for the launch clock if you specify the following command because the `report_timing` command starts reporting from the CK pin:

```
report_timing -from aBC_bs/bs_mex1/r2_00_q1_reg_10_/CK
```

- The first command displays the path leading to the CK pin.
- The following command shows the report generated using the `-unconstrained` parameter:

```
report_timing -unconstrained
```

```

report_timing -from latch/D Settings

The `report_timing -from [register/latch]/CK` command settings can be defined in line with the path reported in `full_clock` path report (as reported path might be `clock->lat/CK->lat/Q->ff2/D`). So the `report_timing -from CK-pin` can be very intuitive.

However, in latch case scenarios where there are multiple D pins on a latch, Tempus supports `-from latch/D` pin, which is generally used for debug purposes. When propagating across `CK->Q` arc, the software will perform worst casing across all the `D->Q` arcs and report the worst path possible. The `report_timing -from latch/D2` command can be used to propagate arrival only across `D2->Q` arc, so that no worst casing occurs. And path report or slack with respect to a particular D pin of latch can be attained.

For example:

- The following command uses `lat/G` (clock pin) , `lat/D` and `lat/D2` (2 data pins) , `lat/Q` (output/begin pin), and shows the below report:

```
report_timing -to ff2/D -path_type full -fields {hpin edge delay arrival arc} -net -from lat/D2
```

```

report_timing_context_clock_mapping

```
report_timing_context_clock_mapping  
[-help]  
[-format <text|csv>]  
[> <fileName>]  
[>> <fileName>]
```

Generates clock mapping report.

By default, Tempus generates the clock mapping report when the `read_timing_context` command is used. The `report_timing_context_clock_mapping` command can be used to generate clock mapping report after `read_timing_context`. This command can generate clock mapping reports in either text format or CSV (helps in easier post-processing of a report).

Parameters

-help	Prints out the command usage.
-format <text csv>	Writes the report in text or csv formats, default is text.
> <fileName>	Writes the report to the specified file name.
>> <fileName>	Writes the report to the specified filename.

Examples

- The given below example shows the `report_timing_context_clock_mapping` command output sample CSV report:

```
# View V1
# Inst I1
# Block Clock, Block Clock Period, Block Clock Waveform, Top Clock, Top Clock Period,
Top Clock Waveform, Port, Comment
# Block clocks mapped to top clocks on clock pins/ports:
BCLK1, 10, {0 5}, TCLK1, 10, {0 5}, CPORT1, auto mapped
BCLK2, 10, {0 5}, TCLK2, 20, {0 10}, CPORT2, user mapped
# Block Clocks NOT Mapped to top clocks on clock pin/ports:
BCLK3, 10, {0 5}, NA, NA, NA, CPORT3, No possible match by parameter
# Top clocks NOT mapped to block clocks on clock pins/ports:
NA, NA, NA, TCLK3, 10, {0 5}, CPORT4, No possible match by parameter
# Virtual block clocks NOT mapped to top clocks:
VCLK1, 10, {0 5}, NA, NA, NA, NA, NA
# Block clocks mapped to top clocks on data ports:
VCLK2, 10, {0 5}, TCLK4, 10, {0 5}, DPORT1, auto mapped
# Block clocks NOT mapped to top clocks on data ports:
VCLK2, 10, {0 5}, NA, NA, NA, DPORT2, No possible match by parameter
# Top clocks NOT mapped to block clocks on data ports:
NA, NA, NA, TCLK5, 10, {0 5}, DPORT3, No possible match by parameter
```

report_timing_derate

```
report_timing_derate
[help]
[-delay_corner delayCornerName]
[-include_inherited]
[collection]
[{> | >>} filename[.gz]]
```

Reports delay scaling or derating factors for early and late clock and data paths in the current design.

By default, the `report_timing_derate` output shows `pulse_width_check` and `clock_period_check` details for instance objects (see `set_timing_derate`).

If you specify this command without any parameters, reports are generated for global derating factors for each instance, net, or cell for which derating is asserted.

The following reports are also generated:

- In best case worst case, maximum and minimum corner
- Early values from minimum corner and late values from maximum corner in on-chip variation mode
- In MMMC mode, specified corners, or for all corners when corner is not specified
- Power domains (if present in the design)
- Derates for pulse width and clock period checks. Also, the report will show mean/sigma values, when the `set_timing_derate -mean/-sigma` parameters are specified.

Parameters

<code>> >> filename</code>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. Note: To write a compressed report, add the <code>.gz</code> extension to the file name.
---------------------------------------	---

<code>-delay_corner delayCornerName</code>	Reports derating factors for the specified delay calculation corner only. <i>Default:</i> Reports derating factors for all delay calculation corners.
<code>-include_inherited</code>	Reports the object names from which the derating factor values are inherited. When specified, the report displays the name of the cell for each instance from which derate values are inherited.
<code>collection</code>	Specifies the list of cells, nets, or library cells.

Examples

- The following command reports derating factors for delay corner `dly_cnr_slow_RX`:

```
tempus > report_timing_derate -delay_corner dly_cnr_slow_RX -include_inherited
```

```
---- Report Timing Derate for DC Corner: dly_cnr_slow_RX
```

```

Related Commands

- `set_timing_derate`

report_timing_lib

```
report_timing_lib  
[-help]  
[-out_file <string>]  
[[[-all | -pin | -threshold | -sibling]  
[cell_name]  
[-by_lib ]] | -library <string>]
```

Reports the contents of the timing library.

Parameters

-help	Prints out the command usage.
-all	Reports all the pin properties, siblings of a cell, the libraries where they are defined, and the voltage.
-by_lib	Organizes the generated report by libraries. If you do not specify this parameter, the <code>report_timing_lib</code> command prints out cells with the same name together. Use this parameter to support multi-supply multi-voltage feature of the software, where you can define same cell names in more than one library with different voltage values and timing data.
<i>cell_name</i>	Specifies the individual cell name to be reported.
-library <i>string</i>	Reports a specified library. If you do not specify this parameter, all the library names are reported.
-pin	Reports the pin properties, such as the pin name, direction, capacitance, max load, max fanout, and fanout load.
-threshold	Reports the input, output, and slew thresholds of a cell.
-sibling	Reports sibling cells, the libraries where they are defined, and the voltage.

`-out_file string`

Specifies the name of the file to which the results are written.

Command Order

Use this command after importing the design when the timing library is also loaded.

Examples

- The following command organizes the generated report by libraries and displays all the cell information:

```
tempus > report_timing_lib -by_lib -all
```

```
Cell: DLH_X1      Library (libset_slow): FrP45_lib_v1.0      0.80000 V.

report_timing_robustness

```
report_timing_robustness  
[-help]  
-check_type {setup | hold | setup_CGS | hold_CGH}  
[-opt_list string]  
[-path_group string]  
-run_time_limit integer  
-target_PTR float  
[-view string]
```

Reports the PTR score of a design.

The Parametric Timing Robustness (PTR) analysis calculates the probability of an entire chip meeting timing requirements, instead of relying on the probabilities on individual paths to compute the robustness of a chip. This command reports the percentage of parts (to be manufactured), which meet timing at all the endpoints.

The PTR score of a design, which is a statistical measure of the timing slack for the whole design, is based on the following steps:

- Enumerates all the instances in a design
- Identifies paths that are critical for PTR of a design
- Computes the PTR-based on Monte-Carlo analysis

Parameters

-help	Prints out the command usage.
-check_type {setup hold setup_CGS hold_CGH}	Specifies the check type.
-opt_list <i>string</i>	Specifies the PTR options list.
-path_group <i>string</i>	Specifies the user-defined path groups created using the group_path command.
-run_time_limit <i>integer</i>	Specifies the runtime limit. Unit in minutes.
-target_PTR <i>float</i>	Specifies the target PTR score.
-view <i>string</i>	Specifies the single view corresponding to the specified check type.

Examples

- The following examples show the calculated PTR value and the report output:

```
report_timing_robustness -check_type setup -path_group R2R -target_PTR 0.8 -  
run_time_limit 15  
collecting paths and reporting PTR .....  
Final PTR 0.89735
```

```
report_timing_robustness -check_type setup -path_group R2R -target_PTR 0.95 -  
run_time_limit 15  
collecting paths and reporting PTR .....  
Final PTR 0.91295
```

```
set P1 [report_timing_robustness -check_type setup -path_group R2R -target_PTR 0.95 -  
run_time_limit 15]  
collecting paths and reporting PTR .....  
Final PTR 0.91295
```

```
report_property $P1

report_timing_summary

```
report_timing_summary  
[-help]  
[-checks {setup | hold | drv | clock}]  
[-expand_clocks {launch_capture | capture_only}]  
[-expand_views]  
[-groups groupname_list]  
[-sort_by {name | wns | tns | fep}]  
[-views viewName]
```

Generates reports that provide details summarized by the violation type - setup, hold, or DRV. You can sort the rows by WNS, TNS, FEP, or by view name.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-checks {setup hold drv clock}</code>	Generates a timing report for the specified check types. The valid values are <code>setup</code> , <code>hold</code> , <code>drv</code> , and <code>clock</code> . <i>Default:</i> <code>setup hold drv clock</code>
<code>-expand_clocks {launch_capture capture_only}</code>	Includes per capture or launch/capture clock group details.
<code>-expand_views</code>	Includes per analysis view details.
<code>-groups groupname_list</code>	Generates a timing report for the specified path group(s). By default, all the path groups are analyzed.
<code>-sort_by {name wns tns fep}</code>	Defines the order in which the report will be sorted - views, clocks, or path groups. The valid values are: • <code>name</code>: Places the items in alphabetical order. • <code>wns</code>: Sorts the output by WNS. • <code>tns</code>: Sorts the output by TNS. • <code>fep</code>: Sorts the output by FEP. <i>Default:</i> <code>name</code>
<code>-views viewName</code>	Generates a timing report for the specified analysis views only. By default all the active views are analyzed.

Examples

- The following command generates a summary report by violation type for the specified view:

```
tempus > report_timing_summary -views scan_slow_RCMIN
```

```
# SETUP                WNS      TNS      FEP
#-----
View : scan_slow_RCMIN  4.922  0.000      0
```

```

      Group : Async          15.286  0.000    0
      Group : in2reg         15.726   0.0    0
#-----
# HOLD                      WNS      TNS    FEP
#-----
View : scan_slow_RCMIN    -0.409  -1.354    15
      Group : Async          3.504   0.000    0
      Group : in2reg        -0.409  -1.354    15

#-----
# DRV                      WNS      TNS    FEP

      Check : min_period                  38.493  0.000    0

#-----

```

- The following command generates a summary report as per launch/capture clock group:

```
tempus > report_timing_summary -views scan_slow_RCMIN -expand_clocks launch_capture
```

```

# SETUP                      WNS      TNS    FEP

Related Commands

- [report_timing](#)

report_wire_load

```
report_wire_load
[-help]
[-instances name_or_collection_of_hierarchical_instances]
[-ports name_or_collection_of_ports]
[-late | -early]
[> | >> filename]
```

Reports the wireload name, library, wire load mode and selection type for all hierarchical instances in the design.

Note: To use the wireload model functionality, you must enable the `enable_wire_load_model_support` attribute using the following command:

```
set_var enable_wire_load_model_support 1
```

Parameters

-help	Prints out the command usage.
> >> <i>filename</i>	When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The <i>filename</i> parameter must be the last argument in the list. Note: To write a compressed report, add the <code>.gz</code> extension to the file name. <i>Default:</i> Report is displayed on standard output without being saved.
-early	Reports wireload model information for the best case condition.

<code>-instances</code> <i>name_or_collection_of_hierarchical_instances</i>	Specifies the name of an instance or collection for which the <code>report_wire_load</code> command reports the wireload name, library, wire load mode, and selection type. The <code>report_wire_load</code> command also supports wildcard names such as U*.
<code>-late</code>	Reports wireload model information in worst-case condition. <i>Data_type</i> : bool, optional
<code>-ports</code> <i>name_or_collection_of_ports</i>	Reports the wireload details for the specified ports.

Examples

- The following command reports the wireload details for the specified ports.

```
report_wire_load -ports clk1 -early
```

```
-----
-----
Design Name      top_chip
Wire Load Mode   enclosed

-----
```

Related Commands

- [set_wire_load_model](#)
- [reset_wire_load_model](#)

reset_instance_library

```
reset_instance_library  
[-help]
```

Resets the settings/binding done using the `set_instance_library` command.

Parameters

<code>-help</code>	Prints out the command usage.
--------------------	-------------------------------

Related Commands

- `set_instance_library`

reset_path_adjust

```
reset_path_adjust
[-help]
-path_adjust_group path_adjust_group_name
-view string
[-setup | -hold]
```

Removes the specified slack adjustment values for timing paths that are set using the `set_path_adjust` command.

Parameters

-help	Prints out the command usage.
-hold	Resets the adjust value for early paths.
-path_adjust_group <i>path_adjust_group_name</i>	Specifies the name of path adjust group that defines the path for which the adjustment will be applied.
-setup	Resets the adjust value for late paths.
-view <i>string</i>	Specifies the view for which adjustment will be reset.

Related Commands

- `set_path_adjust`

reset_path_adjust_group

```
reset_path_adjust_group  
[-help]  
[-name group_name | -all ]
```

Removes all path adjust groups that are set using the `set_path_adjust_group` command for setting path slack adjustment values.

Parameters

-help	Prints out the command usage.
-all	Removes all the path adjust groups.
-name <i>group_name</i>	Removes the named path adjust group completely.

Related Commands

- `set_path_adjust_group`
- `set_path_adjust`

reset_sdf_assertions

`reset_sdf_assertions`

Resets the SDF delays to the values defined in the library. When you perform timing analysis, the software uses the SDF values defined with the `read_sdf` command.

You can use this command to discard the delay values specified with the SDF files, and use the delays defined in the library.

Note: You do not need to read in the SDF delays every time you perform delay calculations. The software uses the SDF files specified earlier in the flow.

Parameters

<code>-help</code>	Prints out the command usage.
--------------------	-------------------------------

Related Commands

- `read_sdf`

reset_timing_derate

```
reset_timing_derate  
[-help]  
[-delay_corner delayCornerName]  
[-increment]  
[-transition]  
[obj_list]
```

Resets derate factors specified on a design or a list of instances (cells, net, or library cells). All the derating factors that are set globally or on specific instances are reset to a default value of 1.0.

Derating factors for early or late paths in the design are set using the [set_timing_derate](#) command.

Parameters

-help	Prints out the command usage.
-delay_corner <i>delayCornerName</i>	Specifies the delay corner or a list of delay corners on which reset derating is to be applied.
-increment	Resets the incremental derate values that are set using the set_timing_derate command. The set_timing_derate command saves two different values – the “base” derate and the “incremental” derate. When the <code>-incremental</code> parameter is used, the software populates the incremental derates. The reset_timing_derate command will reset the incremental derate values only.
<i>obj_list</i>	Specifies the list of cells, nets, or library cells to reset. If the <i>obj_list</i> contains hierarchical cells then all cells within the hierarchical cells and across lower hierarchies have reset derate factors.
-transition	Resets the transition derate values.

Examples

- The following example resets all the object-specific and global derating factors:
`reset_timing_derate *`
- The following example resets only global derating factors:
`reset_timing_derate [current_design]`
- The following example resets derating factor values for the specified delay corner:
`reset_timing_derate -delay_corner delayCornerName`
- The following example resets the global derating values for the specified delay corner:
`reset_timing_derate -delay_corner delayCornerName [current_design]`

Related Commands

- `set_timing_derate`

reset_wire_load_mode

reset_wire_load_mode

Resets the wire-load mode to the default mode of `top`.

Note: To use the wireload model functionality, you must enable the `enable_wire_load_model_support` attribute using the following command:

```
set_var enable_wire_load_model_support 1
```

Related Commands

- `set_wire_load_mode`

reset_wire_load_model

```
reset_wire_load_model
[-help]
[{ obj_list }]
```

Resets wireload models for the specified list of objects. The list of objects can include designs, hierarchical cells, or ports.

When objects are not specified, the software removes the wireload model specified using the `set_wire_load_model` command from the current instance only.

Note: To use the wireload model functionality, you must enable the `enable_wire_load_model_support` attribute using the following command:

```
set_var enable_wire_load_model_support 1
```

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>reset_wire_load_model</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man reset_wire_load_model</code> .
<code>obj_list</code>	Specifies the list of instances or ports for which to remove the wireload models.

Examples

- The following command removes the wireload model for `clk1`:
`reset_wire_load_model clk1`

Related Commands

- `set_wire_load_model`

reset_wire_load_selection_group

```
reset_wire_load_selection_group
[-help]
[{ obj_list }]
```

Removes the wireload selection group for the specified list of objects. The list of objects can include designs, hierarchical cells, or ports. When objects are not specified, wireload selection groups are removed for all objects.

Note: To use the wireload model functionality, you must enable the `enable_wire_load_model_support` attribute using the following command:

```
set_var enable_wire_load_model_support 1
```

Parameters

<code>-help</code>	Prints out the command usage.
<code>obj_list</code>	Specifies the list of object names for which to remove the wireload selection groups.

Examples

- The following command removes the wireload selection group for `clk1`:
`reset_wire_load_selection_group clk1`

Related Commands

- `set_wire_load_selection_group`

select_boundary_model_constraints

```
select_boundary_model_constraints  
[-help]  
[-block string]  
[-define_bundled_bus string]  
[-instance string]  
[-set_instance_library <string>]  
[-set_quiet_attacker string]
```

Applies boundary model constraints to specific blocks/instances.

Parameters

-help	Prints out the command usage.
-block <i>string</i>	Specifies the block for which the constraints will be applied.
-define_bundled_bus <i>string</i>	Applies the <code>define_bundled_bus</code> constraints.
-instance <i>string</i>	Specifies the instance for which the constraints will be applied.
-set_instance_library <string>	Applies the instance library constraints defined with the <code>set_instance_library</code> command.
-set_quiet_attacker <i>string</i>	Applies the <code>set_quiet_attacker</code> constraints.

Related Commands

- `report_boundary_model_constraints`
- `define_bundled_bus`
- `set_quiet_aggressor`
- `set_instance_library`

set_analysis_view

```
set_analysis_view  
[-help]  
[-drv string]  
[-dynamic string]  
[-ir string]  
[-hold string]  
[-leakage string]  
[-setup string]  
[-update_timing]
```

Defines the analysis views to use for setup and hold analysis and optimization. You must define at least one setup and one hold analysis view. The "active" views represent the different design variations that will be analyzed. These views can be changed throughout the flow to utilize different subsets of views. The libraries and data are loaded into the system that are required to support the selected set of active views.

When the `set_analysis_view` command is issued, it will cause a full timing reset. During a timing reset, all the interconnect parasitics, delays, and timing slacks will be recalculated.

The order in which you specify the views with the `-setup` and `-hold` parameters is important. By default, the first views defined in the `-setup` and `-hold` lists are the default views. The default views serve two purposes:

- Provide the library data that is used during the design initialization process.
- Indicate to parts of the application, that are not MMMC-aware, which view's information to use for a particular analysis step (in most cases, the default view is the first setup or hold view). You can use the `set_default_view` command to change the default view to any currently active view without incurring a timing reset. This control is not frequently used since most applications either support MMMC or provide a direct control for selecting the appropriate view to use for that specific analysis.

Using the `set_default_view` command does not affect software performance because it only uses views that are already active in the design. If you use the `set_analysis_view` command to change the default views, the existing timing and delay calculation data is reset.

Use this command after creating multiple analysis views (`create_analysis_view`).

Note: The `set_analysis_view` command does not work in an incremental manner for setting parameters. Each invocation of this command must include the full specification of all the active views required for analysis.

Parameters

-help	Prints out the command usage.
-drv <i>string</i>	Selects specific views for DRV analysis, e.g., max_transition and max_capacitance checking. When this parameter is specified, additional analysis views are specified for DRV analysis, so the timing system efficiently computes the required data for these checks. This methodology is efficient with respect to memory and performance, because all the views as full Setup views are not included. The following guidelines should be followed when selecting DRV views: • Any setup views that require DRV analysis should not be specified as DRV views. The setup views are automatically considered for DRV. • If a subset of hold-only views require DRV analysis, they should be specified as DRV views as well. The timing system will augment the timing information normally computed for Hold views with additional data required for the DRV analysis. • Additional views that are not active setup or hold views can be specified as DRV only views. The system will efficiently compute the required data for performing accurate DRV checks.
-dynamic <i>string</i>	Sets a view as dynamic view. Delay calculation is required to provide transition times. Delay calculation should not perform SI analysis if the delay corner is only required for the dynamic power. The timer is not required to propagate required times or perform slack computations.
-hold <i>list_of_views</i>	Sets the active views for hold analysis.
-ir <i>string</i>	Specifies the IR view.

<code>-leakage string</code>	Sets a view as leakage view. The timing libraries must be loaded, if not already in use. The Timer constant propagation is required, whereas delay calculation is not required.
<code>-setup list_of_views</code>	Sets the active views for setup analysis.
<code>-update_timing</code>	Reloads the configuration described by the MMMC view and mode objects. When the timing attribute <code>timing_defer_mmmc_obj_updates</code> is set to <code>true</code>, this parameter is required to update the MMMC timing environment. The <code>-update_timing</code> parameter may be specified without any <code>-setup</code> or <code>-hold</code> arguments. In this case, the data associated with the current set of setup and/or hold views will be loaded. If no active setup or hold views exist, then using this parameter alone may display an error. The <code>-update_timing</code> parameter may also be used in conjunction with the <code>-setup</code> and <code>-hold</code> options. In this case, the newly specified setup/hold view configuration will be loaded with the updated MMMC object information.

When you issue the `set_analysis_view` command, the software will perform a timing reset, so that only the new active view information is loaded up. The software requires the `-setup` and `-hold` view parameters to be explicitly specified for each `set_analysis_view` command run. If these parameters are not specified, the software issues an error message. Any optional settings, such as, `-leakage` or `-dynamic` views will be reset if they are not specified with the new `set_analysis_view` command.

Note: It is recommended to use the same power view for both leakage and dynamic, that is, both the `-dynamic` and `-leakage` parameters should have the same user-specified view settings.

Examples

- The following command sets `missionWCCOM` and `mission2WCCOM` as the active views for setup analysis, and `missionBCCOM` and `testBCCOM` as the active views for hold analysis:

```
set_analysis_view -setup {missionWCCOM mission2WCCOM} -hold {missionBCCOM testBCCOM}
```

Related Commands

- `create_analysis_view`
- `set_default_view`

set_boundary_model_clock_mapping

```
set_boundary_model_clock_mapping  
[-help]  
-block_clock <string>  
-instance <string>  
-top_clock <string>  
[-view <string>]
```

Provides the boundary model view mapping data.

Parameters

-help	Prints out the command usage.
-block_clock <string>	Specifies the block view.
-instance <string>	Specifies the name of the instance.
-top_clock <string>	Specifies the name of the top clock.
-view <string>	Specifies the name of the view.

Related Commands

- [read_boundary_model](#)
- [set_boundary_model_view_mapping](#)

set_boundary_model_view_mapping

```
set_boundary_model_view_mapping  
[-help]  
-block_view <string>  
-top_view <string>
```

Provides the boundary model view mapping data.

Parameters

-help	Prints out the command usage.
-block_view <string>	Specifies the name of the block view.
-top_view <string>	Specifies the name of the top view.

Examples

- The following command specifies the block view name as `bview`, and the corresponding view name at the top level is `tview`:

```
set_boundary_model_view_mapping -block_view bview -top_view tview
```

Related Commands

- `read_boundary_model`
- `set_boundary_model_clock_mapping`

set_default_view

```
set_default_view
[-help]
{[-hold newDefaultHoldView] | [-setup newDefaultSetupView]}
```

Temporarily changes the default active analysis view to a different active view.

Some Tempus applications can function only on a single analysis view at a time. By default, these single-view applications use the default analysis view. If an application or flow step does not provide a native option for specifying which view to use, the `set_default_view` command can be used to temporarily change the default view to a different active view that is better suited to that flow step.

Note: Using the `set_default_view` command does not affect software performance because it only uses views that are already active in the design. If you use the `set_analysis_view` command to change the default views, the existing timing, delay calculation, and RC data is reset.

Use this command after defining active views for the design (`set_analysis_view`).

Parameters

<code>-help</code>	Prints out the command usage.
<code>-hold newDefaultHoldView</code>	Changes the default active hold analysis view to the specified analysis view.
<code>-setup newDefaultSetupView</code>	Changes the default setup analysis view to the specified analysis view.

Examples

- The following command sets `missionWCCOM`, `mission2WCCOM`, and `missionSlow` as the active views for setup analysis, and `missionBCCOM` and `testBCCOM` as the active views for hold analysis. The default active setup view is `missionWCCOM`, and the default active hold view is `missionBCCOM`.
`set_analysis_view -setup {missionWCCOM mission2WCCOM missionSlow} -hold {missionBCCOM testBCCOM}`
- The following command changes the default active setup view to `missionSlow`:
`set_default_view -setup missionSlow`
- The following command changes the default active hold view to `testBCCOM`:
`set_default_view -hold testBCCOM`

Related Commands

- `create_analysis_view`

set_instance_library

```
set_instance_library  
[-help]  
-library string  
-instance string  
[-early | -late]
```

Binds a cell library to an instance. When specified, the software overrides the default binding mechanism for a cell from the library set.

Note: The `set_instance_library` command cannot be used at the command prompt - this command can be specified in the ViewDefinition file. For more details, refer to the *Tempus User Guide*.

Parameters

-help	Prints out the command usage.
-early	Uses the library binding for early timing analysis.
-instance <string>	Specifies the instance for which the library binding needs to be done.
-late	Uses the library binding for late timing analysis.
-library <string>	Specifies the library file path.

Examples

The following commands specify the instance for which the library binding will be done:

- `set_instance_library -library newcell.lib -instance {i1}`
- `set_instance_library -library mysil.lib -instance {i1 i2}`
- `set_instance_library -library {new.lib mysil.lib} -instance {i1} -early`
- `set_instance_library -library {mynew.lib mysil.lib} -instance {i1 i2} -late`

Related Commands

- `reset_instance_library`

set_interactive_constraint_modes

```
set_interactive_constraint_modes
[-help]
{constraint_mode_list}
```

Puts the software into interactive constraint entry mode for the specified multi-mode multi-corner constraint mode objects. Any timing constraints that you specify after this command take effect immediately on all active analysis views that are associated with the specified constraint modes. By default, no constraint modes are considered active.

All new assertions are saved in the SDC files of the specified constraint modes when you save the design (`write_db`).

Use the `get_interactive_constraint_modes` command to return a list of the constraint mode objects in constraint entry mode.

Note: Interactive constraint mode only works when the software is in multi-mode multi-corner timing analysis mode. In min/max analysis mode, constraints are always accepted interactively.

Parameters

<code>-help</code>	Prints out the command usage.
<code>constraint_mode_list</code>	Specifies the constraint mode objects to update with the new assertions.

Examples

- The following commands put the software into interactive constraint entry mode, and apply the `set_propagated_clock` assertion on all views in the current session that are associated with the constraint mode `func1`:

```
tempus> set_interactive_constraint_modes func1
tempus> set_propagated_clock [all_clocks]
```

When you specify `write_db` command, the updated constraints file for the `func1` constraint mode will include the `set_propagated_clock` constraints.

- The following commands put the software into interactive constraint entry mode, and apply the `set_propagated_clock` assertion on all active analysis views in the current session.

```
tempus> set_interactive_constraint_modes [all_constraint_modes -active]
tempus> set_propagated_clock [all_clocks]
```

When you specify the `write_db` command, the `set_propagated_clock` assertion will be saved persistently as part of a new `.sdc` file.

Related Commands

- `get_interactive_constraint_modes`
- `get_db`
- `write_db`

set_io_thresholds

```
set_io_thresholds
[-help]
[-slew_lower_threshold_pct pctValue]
[-slew_upper_threshold_pct pctValue]
[-input_threshold_pct pctValue]
[-output_threshold_pct pctValue]
[-slew_lower_threshold_pct_rise pctValue]
[-slew_lower_threshold_pct_fall pctValue]
[-slew_upper_threshold_pct_rise pctValue]
[-slew_upper_threshold_pct_fall pctValue]
[-input_threshold_pct_rise pctValue]
[-input_threshold_pct_fall pctValue]
[-output_threshold_pct_rise pctValue]
[-output_threshold_pct_fall pctValue]
```

Sets the threshold trip-points used for delay calculation to and from the primary I/Os. The `set_io_thresholds` command does not affect the interpretation of threshold settings in the Liberty timing libraries; the effect is strictly limited to the I/O ports.

If you do not specify I/O thresholds with the `set_io_thresholds` command, delay calculation assumes that the I/O thresholds are equivalent to those of the logic gates to which they are connected.

The `set_io_thresholds` command supports separate rise and fall slew thresholds as normally found in Liberty timing libraries.

Note: Some third-party applications derive the I/O threshold values from the first Liberty timing library in the library search path. The software currently does not support this methodology. Explicit setting of I/O thresholds with the `set_io_thresholds` command should be used to complete a compatible analysis environment.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-input_threshold_pct <i>pctValue</i></code>	Specifies the slew input threshold value.
<code>-input_threshold_pct_fall <i>pctValue</i></code>	Specifies the measurement point for a falling signal that will be used for calculating the interconnect delay from a primary input to internal logic. <i>Value:</i> 0 - 100 <i>Default:</i> 50

<code>-input_threshold_pct_rise pctValue</code>	Specifies the measurement point for a rising signal that will be used for calculating the interconnect delay from a primary input to internal logic. <i>Value:</i> 0 - 100 <i>Default:</i> 50
<code>-output_threshold_pct pctValue</code>	Specifies the slew output threshold value.
<code>-output_threshold_pct_fall pctValue</code>	Specifies the measurement point for a falling signal that will be used for calculating the interconnect delay from internal logic to a primary output. <i>Value:</i> 0 - 100 <i>Default:</i> 50
<code>-output_threshold_pct_rise pctValue</code>	Specifies the measurement point for a rising signal that will be used for calculating the interconnect delay from internal logic to a primary output. <i>Value:</i> 0 - 100 <i>Default:</i> 50
<code>-slew_lower_threshold_pct pctValue</code>	Specifies the slew lower threshold value.
<code>-slew_lower_threshold_pct_fall pctValue</code>	Specifies the lower trip-point for a falling signal that will be used to measure transition times. <i>Value:</i> 0 - 100 <i>Default:</i> 20
<code>-slew_lower_threshold_pct_rise pctValue</code>	Specifies the lower trip-point for a rising signal that will be used to measure transition times. <i>Value:</i> 0 - 100 <i>Default:</i> 20
<code>-slew_upper_threshold_pct_fall pctValue</code>	Specifies the upper trip-point for a falling signal that will be used to measure transition times. <i>Value:</i> 0 - 100 <i>Default:</i> 80

<code>-slew_upper_threshold_pct_rise <i>pctValue</i></code>	Specifies the upper trip-point for a rising signal that will be used to measure transition times. <i>Value:</i> 0 - 100 <i>Default:</i> 80
<code>-slew_upper_threshold_pct <i>pctValue</i></code>	Specifies the slew upper threshold value.

Examples

- The following command specifies trip-points for measuring delay and transition times:

```
set_io_thresholds -slew_lower_threshold_pct_rise 10
```

```
-slew_upper_threshold_pct_fall 80
```

```
-slew_upper_threshold_pct_rise 90
```

```
-slew_lower_threshold_pct_fall 20
```

```
-input_threshold_pct_rise 40
```

```
-input_threshold_pct_fall 70
```

```
-output_threshold_pct_rise 60
```

```
-output_threshold_pct_fall 30
```

set_ipd_rail_voltage

```
set_ipd_rail_voltage  
[-help]  
[-exclude_voltage_signatures <List of combinations to be excluded>]  
[-add | -sweep <List of power rails and corresponding voltage sweep list>]
```

Specifies the PG net voltage and excludes those voltage combinations that do not require analysis. When power intent is specified through CPF/IEEE-1801, the `set_ipd_rail_voltage` specification refers to the primary power net of power domain.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-add</code>	Specified with the <code>-exclude_voltage_signatures</code> parameter to exclude voltage combinations incrementally.
<code>-exclude_voltage_signatures <List of combinations to be excluded></code>	Specifies the list of voltage combinations to be excluded from all the possible combinations of voltage.
<code>-sweep <List of power rails and corresponding voltage sweep list></code>	Specify the list of power rails and their corresponding voltage values.

Examples

- The following command is used to specify the PG nets in the design and the corresponding voltages (in volts):

```
tempus > set_ipd_rail_voltage -sweep { PGN1 {0.7 0.8} PGN2 {0.9 1.0} PGN3 {1.1 1.2} PGN4 {0.6 0.7} }
```
- The following command removes a particular combination from the analysis:

```
tempus > set_ipd_rail_voltage -exclude_voltage_signatures { {PGN1 0.7 PGN2 0.9 PGN3 1.2 PGN4 0.6} }
```
- The following command excludes more combinations:

```
tempus > set_ipd_rail_voltage -exclude_voltage_signatures { {PGN1 0.7 PGN2 0.9 PGN3 1.2 PGN4 0.7} } -add
```

set_max_cap_per_freq

```
set_max_cap_per_freq  
[-help]  
-cap {cap1 cap2 ...}  
[-force]  
-freq {freq1 freq2 ...}  
[-lib lib_name]  
-pins {cell pin}
```

Adds a maximum capacitance per frequency table to the existing `max_capacitance` statement in the timing library. Timing analysis uses this table to detect violations and the software attempts to repair violations.

The timing engine derives the frequency of an instance from the clock domain to which it is connected (the fastest clock domain, if there is more than one). If the instance is a clock instance (that is, part of the clock tree), the actual clock frequency is used. If the instance is part of the combinational logic (that is, a flip-flop, or the logic connected to the output of a flip-flop), the frequency used equals one-half of the associated clock domain frequency because a flip-flop output can only toggle at one-half the rate of the input clock. For example, a clock of 1.0 Mhz has 1,000,000 rise and fall transitions per second; however the output of a flip-flop connected to a 1.0 Mhz clock can only have 500,000 rise and fall transitions per second.

Timing analysis computes the frequency directly from the timing graph.

You can use this command any time after loading the timing library files (that is, after importing or restoring the design).

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>set_max_cap_per_freq</code> parameter. For a detailed description of the command and all of its parameters, use <code>man set_max_cap_per_freq</code>.
<code>-cap</code> <code>{cap1cap2 ...}</code>	Specifies a list of capacitance values that must be greater than or equal to 0. You must specify the same number of <code>-freq</code> and <code>-cap</code> values. The software derives the maximum capacitance from a linear interpolation (or extrapolation) for a given frequency value using two frequency values in the table. For interpolation, the software uses the closest value above the frequency, and the closest value below the frequency. For extrapolation, the software uses the two closest values to the frequency. <i>Type:</i> Float, specified in units of pF
<code>-force</code>	Computes the maximum capacitance from the interpolated <code>-freq</code> and <code>-cap</code> values only, and ignores any previously defined <code>max_capacitance</code> values for these pins in the library. <i>Default:</i> Computes the maximum capacitance using the worst case (minimum value) between the library <code>max_capacitance</code> values and the interpolated <code>-cap</code> values.
<code>-freq</code> <code>{freq1freq2 ...}</code>	Specifies a list of at least two frequency values that must be greater than or equal to 0. You must specify the same number of <code>-freq</code> and <code>-cap</code> values, and the frequency values must be specified in ascending order. <i>Type:</i> Float, specified in units of Hz
<code>-lib libName</code>	Modifies only the matching cell-pins in the specified library. <i>Default:</i> Modifies the matching cell-pins in all libraries
<code>-pins</code> <code>{cellpin}</code>	Adds the new capacitance constraints to the specified set of cells and pins. You can specify output or inout pins. The asterisk (*) wildcard character can be used in a cell or pin name. If a table associated with the pin already exists, it is replaced with the new table. For analysis and optimization, the software uses the most restrictive (the lowest capacitance) value from either the table or the <code>.lib max_capacitance</code>. If you also specify the <code>-force</code> parameter, the <code>max_capacitance</code> value is ignored. The final value can be further modified using <code>.sdc set_max_capacitance</code> statements.

Command Order

Use this command any time after loading the timing library files (that is, after importing or restoring the design).

Examples

Assume all output pins of a library have a `max_capacitance` of 3.5 pF from the library file.

- The following command sets the frequency dependent `max_capacitance` to 3.0 pF at a frequency of 100 Mhz, and to 1.5 pF at a frequency of 200 Mhz, for all output or inout pins for all cells in the library named `fast`:

```
tempus> set_max_cap_per_freq -lib fast -freq {100e6 200e6} -cap {3.0 1.5} -pins {* *}
```

As a result, for a net at 300 Mhz, an and2 cell output pin has an extrapolated `max_capacitance` value of 0 pF (which means the cell cannot be used at that frequency). An extrapolation to 50 Mhz results in a `max_capacitance` value of 3.75 pF. However, the 3.75 pF value is greater than the existing `.lib max_capacitance` limit of 3.5 pF; therefore timing analysis uses the 3.5 pF value.

- The following command applies the same constraints to all libraries with cell names matching `dff*` that have a pin named `Qbar`:

```
tempus> set_max_cap_per_freq -force -freq {100e6 200e6} -cap {3.0 1.5} -pins {dff*  
Qbar}
```

Note: The original `.lib max_capacitance` limit is ignored because the `-force` parameter is specified; therefore extrapolation to 50 Mhz results in a final `max_capacitance` constraint value of 3.75 pF.

Related Commands

- `set_max_transition_per_freq`

set_max_cap_per_freq_transition

```
set_max_cap_per_freq_transition
[-help]
-cap { {cap11 cap12 cap13...} {cap21 cap22 cap23} {cap31 cap32 cap33...}}
[-force]
-freq {freq1 freq2 freq3...}
[-input_pin inputpin]
[-lib libName]
-pins {cell outputpin}
-transition {freq1 freq2 ...}
```

Sets the maximum capacitance of a pin in the design. Considers both the input transition time and the output frequency. If the maximum capacitance exceeds this value, the `report_constraint -drv_violation_type max_capacitance` command displays a capacitance violation.

You can use this command any time after loading the timing library files (that is, after importing or restoring the design).

Parameters

-help	Outputs a brief description that includes type and default information for each <code>set_max_cap_per_freq_transition</code> parameter. For a detailed description of the command and all of its parameters, use <code>man set_max_cap_per_freq_transition</code>.
-cap {{cap11cap12 cap13...} {cap21 cap22 cap23...} {cap31 cap32 cap33...}}	Specifies a table of capacitance values with the maximum output pin capacitances associated with <code>-freq</code> and <code>-transition</code> values. The total number of <code>-cap</code> values must be the total number <code>-freq</code> values times the total number of <code>-transition</code> values. The <code>-freq</code> and <code>-transition</code> values must be specified before <code>-cap</code>. The capacitance values are floats in units of pico farad and all values must be greater than or equal to zero. The capacitance table uses frequency as the first index and the input transition as the second index. For example, <code>cap11</code>, <code>cap12</code>, and <code>cap13</code> are for <code>freq1</code>, while <code>c12</code>, <code>c22</code>, and <code>c32</code> correspond to the input transition <code>tran2</code>. The maximum capacitance is derived from a linear interpolation (or extrapolation) for a given frequency value and a transition value using two frequency values and two transition values in the table (closest above and below for interpolation, the two closest for extrapolation). <i>Type:</i> Float, specified in units of pF

<code>-force</code>	Computes the maximum capacitance from the interpolated <code>-freq</code>, <code>-transition</code>, and <code>-cap</code> values only, and ignores any previously defined <code>max_capacitance</code> values for these pins in the library. <i>Default:</i> (<code>-force</code> not specified) Computes the maximum capacitance using the worst case (minimum value) between the library <code>max_capacitance</code> values and the interpolated <code>-cap</code> values.
<code>-freq {freq1freq2 freq3...}</code>	Specifies a list of at least two frequency values with the toggle frequencies at the output pin. Frequency values must be increasing, and the total number of frequency values cannot exceed 255. <i>Type:</i> Float, specified in units of Hz. All values must be equal to or greater than 0.
<code>- input_pin inputpin</code>	Specifies the input pin name corresponding to the input transition values in as specified using the <code>-transition</code> parameter. If the <code>-inputpin</code> parameter is not specified, then <code>-transition</code> parameter values correspond to all the input pins.
<code>-lib libName</code>	Specifies the library name from inside a <code>.lib</code> file to update the cell-pins. <i>Default:</i> If a library name is not specified, modifies the matching cell-pins in all libraries
<code>-pins {cell outputpin}</code>	Adds the new capacitance constraints to the specified set of cells and pins. You can specify output or inout pins; input pins are ignored. The asterisk (*) wildcard character can be used in a cell or pin name. If there is already a table associated with the same input-output pair (input pins are specified using <code>-input_pin</code>), it is replaced with the new constraints; otherwise, it is added to the output maximum capacitance table list. For analysis and optimization, the software uses the most restrictive (the lowest capacitance) value from either the table or the <code>.libmax_capacitance</code>. If you also specify the <code>-force</code> parameter, the <code>max_capacitance</code> value is ignored. The final value can be further modified using <code>.sdc set_max_capacitance</code> statements.
<code>-transition {freq1 freq2 ...}</code>	Specifies a list of at least two transition values with the input transition times. Transition times must be increasing in value, and the total number of transition times cannot exceed 255. <i>Type:</i> Float, specified in units of nanoseconds, and all values must be equal to or greater than 0.

Examples

- The following command establishes a maximum capacitance table for all pins and on all the cells in the libraries:

```
set_max_cap_per_freq_transition -force -pins {*} *} -freq {1e8 1.25e8 1.5e8} \  
-transition {450 475 500} -cap {{0.022 0.017 0.012} {0.02 0.014 0.01} {0.018 0.013  
0.008}}
```

The table is shown below:

	450	475	500
1e8	0.022	0.017	0.012
1.25e8	0.02	0.014	0.01
1.5e8	0.018	0.013	0.008

Related Commands

- `set_max_cap_per_freq`
- `set_max_transition_per_freq`
- `report_constraint`

set_max_transition_per_freq

```
set_max_transition_per_freq  
[-help]  
[-force]  
-freq <string>  
[-lib <string>]  
-pins <string>  
-transitions <string>
```

Adds a maximum transition per frequency table to the existing max_transition statement in the timing library. Timing analysis uses this table to detect violations, and the software attempts to repair those violations.

Use this command any time after loading the timing library files (that is, after importing or restoring the design).

The timing engine derives the frequency of an instance from the clock domain to which it is connected (the fastest clock domain, if there is more than one). If the instance is a clock instance (that is, part of the clock tree), the actual clock frequency is used. If the instance is part of the combinational logic (that is, a flip-flop, or the logic connected to the output of a flip-flop), the frequency used equals one-half of the associated clock domain frequency because a flip-flop output can only toggle at one-half the rate of the input clock. For example, a clock of 1.0 Mhz has 1,000,000 rise and fall transitions per second; however the output of a flip-flop connected to a 1.0 Mhz clock can only have 500,000 rise and fall transitions per second.

Timing analysis computes the frequency directly from the timing graph. Use the `check_ac_limits -toggle` command to write the effective frequency onto the associated net in the database.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>set_max_transition_per_freq</code> parameter. For a detailed description of the command and all of its parameters, use <code>man set_max_transition_per_freq</code>.
<code>-force</code>	Computes the maximum transition from the interpolated <code>-freq</code> and <code>-transition</code> values only and ignores any previously defined <code>max_transition</code> values for these pins in the library. <i>Default:</i> Uses the worst case (minimum value) between the <code>.libmax_transition</code> values and the interpolated <code>-transition</code> values.
<code>-freq string</code>	Specifies a list of at least two frequency values that must be greater than or equal to 0. You must specify the same number of <code>-freq</code> and <code>-transition</code> values, and the frequency values must be specified in ascending order. <i>Type:</i> Float, specified in units of Hz
<code>-lib string</code>	Modifies only the matching cell-pins in the specified library. <i>Default:</i> Modifies the matching cell-pins in all libraries.
<code>-pins string</code>	Adds the new transition constraints to the specified set of cells and pins. You can specify input, output, or inout pins. The asterisk (*) wildcard character can be used in a cell or pin name. If a table associated with the pin already exists, it is replaced with the new table. For analysis and optimization, the software uses the most restrictive (the lowest transition) value from either the table or the <code>.lib max_transition</code>. If you also specify the <code>-force</code> parameter, the <code>max_transition</code> value is ignored. The final value can be further modified using <code>.sdc set_max_transition</code> statements.
<code>-transitions string</code>	Specifies a list of transition values that must be greater than or equal to 0. You must specify the same number of <code>-freq</code> and <code>-transition</code> values. The software derives the maximum transition limit from a linear interpolation (or extrapolation) for a given frequency value using two frequency values in the table. For interpolation, the software uses the closest value above the frequency, and the closest value below the frequency. For extrapolation, the software uses the two closest values to the frequency. <i>Type:</i> Float, specified in units of ns

Examples

Assume all output pins of a library have a `max_transition` value of 0.9 ns from the library file.

- The following command sets the frequency dependent `max_transition` to 1.0 ns at a frequency of 100 Mhz, and to 0.7 ns at a frequency of 200 Mhz, for pins matching `in*` of cells matching `*` (that is, all cells) in the library named `slow`:

```
set_max_transition_per_freq -lib slow -freq {100e6 200e6} -transitions {1.0 0.7} -pins  
{* in*}
```

As a result, at 300 Mhz, an `and2` cell input pin named `in1` has an extrapolated `max_transition` value of 0.4ns. An extrapolation to 50 Mhz results in a `max_transition` value of 1.15 ns. However, the 1.15 ns value is greater than the existing `.lib max_transition` value of 0.9 ns; therefore timing analysis uses the 0.9 value.

- The following command applies the same constraints to all libraries with cell names matching `dff*` that have a pin named `clk`:

```
set_max_transition_per_freq -force -freq {100e6 200e6} -transitions {1.0 0.7} -pins  
{dff* clk}
```

Note: The original `.lib max_transition` value is ignored because the `-force` parameter is specified; therefore an extrapolation to 50 Mhz results in a final `max_transition` limit of 1.15 ns.

Related Commands

- `set_max_cap_per_freq`

set_multi_input_switching_mode

```
set_multi_input_switching_mode  
[-help]  
[-disable_lib_cells <string>]  
[-mis_alignment_mode {0 | 1}]  
[-switching_alignment_factor <float>]  
[-view <string>]
```

Configures multi-input switching (MIS) mode settings.

You can enable the MIS feature using the `timing_analysis_multi_input_switching_mode` attribute.

For reporting advanced MIS in delay calculation and delta delay in timing reports, you can use the following options:

- `report_delay_calculation -mis`
- `report_timing -fields retime_mis_delta`
- `timing_report_fields {retime_mis_delta}`

Parameters

<code>-help</code>	Prints out the command usage.
<code>-disable_lib_cells</code> <code><string></code>	Enables or disables the multi-input switching (MIS) mode support for the specified library cells. <i>Default:</i> " "
<code>-mis_alignment_mode {0 1}</code>	Controls the MIS alignment mode. <i>Default:</i> 0
<code>-switching_alignment_factor</code> <code><float></code>	Allows to configure the relative alignment of side inputs switching with respect to the primary inputs. The switching alignment factor is applied for all the instances for which MIS analysis is to be performed. This parameter accepts values between -1 to 1. These are described below: • 1: Side inputs switch at the earliest arrival. • 0: Side inputs switch at the same time as actual input. • -1: All the side inputs switch at the same time and align at the completion of the output pin transition. <i>Default:</i> 0 Note: Setting the <code>-switching_alignment_factor</code> to 1 can be pessimistic if a side input switches much earlier than the main input. You can use the <code>-mis_alignment_mode</code> parameter to reduce pessimism in this mode.
<code>-view <string></code>	Specifies the name of the view.

Examples

- The following commands disable MIS support for the specified library cells:

```
set_multi_input_switching_mode -disable_lib_cells [get_libs_cell aoi*]
set_multi_input_switching_mode -disable_lib_cells [get_libs_cell lib_0.510v/aoi*]
```

set_opcond

```
set_opcond
[-help]
[-forceLibrary libName]
[-library libName]
[-min minOpCond [-minLibrary minLib]]
[-max maxOpCond [-maxLibrary maxLib]]
[<opCond <opCond>>]
[-powerDomain string]
```

Sets the operating temperature, process, or voltage conditions for the design. The operating conditions are contained in the timing library, which are normally read in during design import.

The `set_opcond` command can use a virtual operating condition that was created with the multi-mode multi-corner `create_opcond` command.

Parameters

-help	Prints out the command usage.
-forceLibrary libName	Specifies the library in which the <i>opCond</i> will be set. Do not use this parameter with the <code>-min</code> , <code>-max</code> , or <code>-powerDomain</code> parameters. Use this parameter to specify different operating conditions for different libraries in a single session.
-library libName	Specifies the library in which the operating condition (<i>opcond</i>) is defined. You can define a single operating condition from a library, and the software uses the PVT characteristics associated with that library for every library in the design. When you use this parameter in multiple <code>set_opcond</code> commands, the software uses the value specified in the last command. If the <code>-library</code> parameter is not specified, the <i>opCond</i> in the first library read is used. For example, consider the following commands: <pre>set_opcond WCCOM -library wcTestLib set_opcond BCCOM -library bcTestLib set_opcond WCCOM -library wcTestLib1 set_opcond BCCOM -library bctestLib1 set_opcond -library wcTestLib2 set_opcond -library bcTestLib2</pre> In this case, the software uses the last value defined (<code>bcTestLib2</code>). Therefore, the operating conditions in the <code>bcTestLib2</code> library are used for both setup and hold analysis.

<code>-max</code> <i>maxOpCond</i>	Specifies the operating condition normally used for setup analysis.
<code>-maxLibrary</code> <i>maxLib</i>	Specifies the library in which the <i>maxOpCond</i> is defined. If the <code>-maxLibrary</code> parameter is not specified and <code>-max</code> is used, the <i>maxOpCond</i> from the first library listed in the maximum libraries is used.
<code>-min</code> <i>minOpCond</i>	Specifies the operating condition normally used for hold analysis.
<code>-minLibrary</code> <i>minLib</i>	Specifies the library in which the <i>minOpCond</i> is defined. If the <code>-minLibrary</code> parameter is not specified and <code>-min</code> is used, the <i>minOpCond</i> from the first library listed in the minimum libraries is used.
<code><opCond</code> <code><opCond>></code>	Specifies the operating condition used for setup and hold analysis. You can specify a virtual operating condition created with the multi-mode multi-corner create_op_cond command.
<code>-powerDomain</code> <i>string</i>	Specifies that the <i>opCond</i> is used for the power domain.

Command Order

Use this command after importing the design and reading the libraries.

Examples

- The following command sets the operating condition of the design to `WCCOM` defined in the `slowLib` timing library. The worst case (WCCOM) operation condition will be used for both setup and hold analysis:

```
tempus> set_opcond WCCOM -library slowLib
```
- The following Tcl command sets the operating condition to `WCCOM` defined in the `slowlib` library for setup analysis and sets the operating condition to `BCCOM` defined in the `fastlib` library for hold analysis:

```
tempus> set_opcond -max WCCOM -maxLibrary slowlib -min BCCOM -minLibrary fastlib
```
- The following example specifies the `slow` operating condition defined in the `slow` library for setup analysis and the `fast` operating condition defined in the `fast` library for hold analysis:

```
tempus> set_opcond -maxLibrary slow -max slow -minLibrary fast -min fast
```
- The following example sets the timing libraries to associate the fast library (Min Libraries) to setup

and the slow library (Max Libraries) to hold:

```
tempus> set_timing_library -max Min -min Max
```

However, this means that setup analysis uses the `fast` library (defined in the Min Libraries list) with a `slow` operating condition defined in the `slow` library, and hold analyses uses the `slow` library (defined in the Max Libraries list) but with a `fast` operating condition defined in the `fast` library. To get a consistent result, reset the `set_opcond` command to:

```
tempus> set_opcond -maxLibrary fast -max fast -minLibrary slow -min slow
```

Now setup analysis uses the `fast` library (defined in the Min Libraries list) with a `fast` operating condition defined in the `fast` library, and hold analyses uses the `slow` library (defined in the Max Libraries list) but with a `slow` operating condition defined in the `slow` library.

Related Commands

set_path_adjust

```
set_path_adjust
[-help]
adjust_value
-path_adjust_group path_adjust_group_name
-view string
[-setup | -hold]
```

Defines the slack adjustment value for timing paths. The defined adjustment value is added to the slack of a path specified by the path adjust group, referred to by the `-path_adjust_group` parameter. You can specify a path adjust group by using the `set_path_adjust_group` command.

If multiple path adjustment values are applicable on the same pin, which is on the path specified by multiple `set_path_adjust_group` constraints, then the smallest adjustment value will be applied.

Note: The `set_path_adjust` command is not allowed to be used inside the SDC constraints file. It is only allowed in the software run script.

Parameters

<code>-help</code>	Prints out the command usage.
<code>adjust_value</code>	Specifies the value of slack adjustment.
<code>-hold</code>	Specifies to apply the adjust value to early paths.
<code>-path_adjust_group</code> <code>path_adjust_group_name</code>	Specifies the name of path adjust group that defines the path for which the adjustment will be applied.
<code>-setup</code>	Specifies to apply the adjust value to late paths. Note: If you do not specify <code>-setup</code> or <code>-hold</code> parameter, the software sets the adjust value to both setup and hold analysis.
<code>-view string</code>	Specifies a list of analysis views for which adjustment will be applied. This parameter accepts multiple views as argument.

Examples

- The following commands define the slack adjustment values for the specified views:

```
tempus> set_path_adjust 0.44 -path_adjust_group AG1 -view view1 -hold
```

```
tempus> set_path_adjust 0.44 -path_adjust_group AG2 -view view2 -setup
```

```
tempus> set_path_adjust 0.44 -path_adjust_group AG3 -view view3
```

Related Commands

- [set_path_adjust_group](#)

set_path_adjust_group

```
set_path_adjust_group  
[-help]  
[-fall]  
[-fall_through through_list]  
-name path_adjust_group_name  
[-rise]  
[-rise_through through_list]  
[-through through_list]  
[-from from_list | -rise_from from_list | -fall_from from_list]  
[-to to_list | -rise_to to_list | -fall_to to_list]
```

Allows you to specify the path that is used by the [set_path_adjust](#) command for setting path slack adjustment values.

The `set_path_adjust_group` command is not allowed to be used inside the SDC constraints file. It is only allowed in the tool run script.

If path group definitions are matching/overlapping (when the `-from/-through/-to` parameters are used), then path group resetting is applied. The path group overwriting and prioritization rules are similar to path exceptions.

For more details, refer to [group_path](#).

Parameters

<code>-help</code>	Prints out the command usage.
<code>-fall</code>	Applies <code>set_path_adjust_group</code> at the falling edge of the signal on the path endpoints.
<code>-fall_from from_list</code>	Applies <code>set_path_adjust_group</code> at the falling edge of the signal on the from pins.
<code>-fall_through through_list</code>	Applies <code>set_path_adjust_group</code> at the falling edge of the signal on the through pins.
<code>-fall_to to_list]</code>	Applies <code>set_path_adjust_group</code> at the falling edge of the signal on the to pins.
<code>-from from_list</code>	Specifies the list of pins, instances, or clocks that are the start of the paths.
<code>-name path_adjust_group_name</code>	Specifies the name of the path adjust group.
<code>-rise</code>	Applies <code>set_path_adjust_group</code> at the rising edge of the signal on the path endpoints.
<code>-rise_from from_list</code>	Applies <code>set_path_adjust_group</code> at the rising edge of the signal on the from pins.
<code>-rise_through through_list</code>	Applies <code>set_path_adjust_group</code> at the rising edge of the signal on the through pins.
<code>-rise_to to_list</code>	Applies <code>set_path_adjust_group</code> at the rising edge of the signal on the to pins.
<code>-through through_list</code>	Specifies the list of pins or instances where the paths go through.
<code>-to to_list</code>	Specifies the list of pins, instances, or clocks where the path ends.

Examples

The following commands specify the adjusted path groups:

- `set_path_adjust_group -name AG1 -from in1 -through buf1/A -to out1`
- `set_path_adjust_group -name AG2 -from [get_clocks CK1] -through buf1/A -to [get_clocks CK2]`

- `set_path_adjust_group -name AG3 -from [get_clocks {CK1 CK2}] -to [get_clocks {CK1 CK2}]`

Related Commands

- `reset_path_adjust_group`
- `set_path_adjust`
- `group_path`

set_socv_constraint_config

```
set_socv_constraint_config  
[-help]  
[-hold_folding float]  
{-libs <string>}  
[-nochange_hold_folding float]  
[-nochange_setup_folding float]  
[-setup_folding float]
```

Enhances the built-in sigma pessimism of check values for setup and hold constraints in the library. The folding factor attribute records the amount of on-chip-variation pessimism added during cell characterization to the nominal setup/hold tables in the libraries. The folding factor attributes are library level attributes.

Notes

- The `set_socv_constraint_config` command does not reset the timing; so it should be used before the `report_timing` command.
- To change the setting later in the flow, you need to use the `update_timing -full` command.
- You cannot use this command, if any of the following attributes are specified:

```
timing_library_setup_sigma_multiplier  
timing_library_hold_sigma_multiplier
```

Parameters

<code>-help</code>	Prints out the command usage.
<code>-hold_folding float</code>	Specifies a number of additional sigma units added on top of the existing nominal hold value. <i>Min</i> = -100 <i>Max</i> = 100
<code>-libs string</code>	Specifies a list of library names (not library paths) or collection objects.
<code>-nochange_hold_folding float</code>	Specifies a number of additional sigma units added on top of the existing nominal hold value for no-change timing arcs. <i>Min</i> = -100 <i>Max</i> = 100
<code>-nochange_setup_folding float</code>	Specifies a number of additional sigma units added on top of the existing nominal setup value for no-change timing arcs. <i>Min</i> = -100 <i>Max</i> = 100
<code>-setup_folding float</code>	Specifies a number of additional sigma units added on top of the existing nominal setup value. <i>Min</i> = -100 <i>Max</i> = 100

Examples

- The following command is used when an additional margin of 10 sigma units is applied to the nominal hold tables in the library collection test.lib:

```
set_socv_constraint_config -hold_folding 10 -libs [get_libs test.lib]
```

Related Commands

- `report_timing`
- `update_timing`

set_socv_rc_variation_factor

```
set_socv_rc_variation_factor  
[-help]  
value  
[-early]  
[-late]  
[-views list_of_views]
```

Defines the value of interconnect delay variation factor.

This command applies global variation as percentage of the nominal delay.

To enable this feature, you can set the `timing_socv_rc_variation_mode` attribute to `true`.

Parameters

<code>-help</code>	Prints out the command usage
<code>value</code>	Specifies the value of the interconnect delay variation factor to be used.
<code>-early</code>	Specifies the variation factor for early interconnect delays.
<code>-late</code>	Specifies the variation factor for late interconnect delays.
<code>-views</code> <code><i>list_of_views</i></code>	Apply the SOCV interconnect variation factor to the specified list of analysis views.

Related Commands

- `get_socv_rc_variation_factor`

set_socv_reporting_nsigma_multiplier

```
set_socv_reporting_nsigma_multiplier  
[-help]  
[-views list_of_views]  
{[-setup float] [-hold float]}  
[-transition float]
```

Controls n-sigma value for reporting purposes.

This command supports n-sigma specification per view per setup/hold combination.

Parameters

-help	Prints out the command usage.
-hold <i>float</i>	Specifies the sigma multiplier for hold mode.
-setup <i>float</i>	Specifies the sigma multiplier for setup mode.
-transition <i>float</i>	Specifies the sigma multiplier to use for transition related DRV checks – including max_transition, min_transition, pulse_clock_max_transition, and pulse_clock_min_transition. When this parameter is not specified, the sigma multiplier specified for setup will be used for transitions. When the -transition parameter is specified, you can set the timing_report_max_transition_check_using_nsigma_slew attribute to true to report transition related DRV checks, such as, max_transition, min_transition, pulse_clock_max_transition, and pulse_clock_min_transition. This setting enables the report_constraint command to use mean and sigma slew values for reporting transition values in DRV checks.
-views <i>list_of_views</i>	Applies the sigma multiplier factor to the specified list of analysis views. Note: The specified views should be active.

Examples

- The following command applies the sigma multiplier to the specified view in setup mode :
tempus > set_socv_reporting_nsigma_multiplier -setup 2.5 -view std_max_setup
- The following command applies the sigma multiplier to the specified view in for hold mode:
tempus > set_socv_reporting_nsigma_multiplier -hold 3.0 -view std_min_hold

Related Commands

- `get_socv_reporting_nsigma_multiplier`

set_table_style

```
set_table_style
-help
-name string
[-major_sort integer]
[-minor_sort integer]
[-max_widths integer]
[-min_widths integer]
[-indent integer]
[-nosplit]
[-reverse_rows] | -no_frame_fix_width
```

Disables printing of specific columns and allows for specifying the minimum and maximum size of each column in a report. It allows for reversing the data, for controlling the left indent, and for controlling the sorting of the columns.

Note: Do *not* include a blank space between commas "," when specifying widths. If you are specifying a value for the width(s), make sure there is *no* leading or trailing blank space.

The `-frame`, `-no_frame`, and `-no_frame_fix_width` parameters work in a global manner. If you specify one of these parameters, it will affect all reports that can be formatted with this command. You cannot specify them with the `-name` parameter, to change the format of a specific report.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>set_table_style</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man set_table_style</code> .
<code>-frame</code>	Specifies that the table columns have a fixed frame or border, based on the minimum and maximum width settings. Any data that is longer than the maximum width for its column is wrapped within the same column. This is the default format for tables.
<code>-indent <i>integer</i></code>	Specifies the number of spaces to leave on the left for that particular table.
<code>-major_sort <i>integer</i></code>	Specifies the column to be used in the major sort. If the column number is negative, it reverses the sort.

`-max_widths integer`

Specifies the maximum width for each table column in the report specified by the `-name` parameter.

Note: You cannot specify `-max_widths` parameter without `-name`.

You can separate each specified width value with a comma (,). For example, if you specify:

```
-max_widths {10,20,30}
```

The first column will have a maximum width of 10, the second column will have a maximum width of 20, and the third column will have a maximum width of 30. The fourth and fifth columns will remain the default width spacing.

Commas are also specified as column "placeholders", when you want to change the spacing of a column without changing the spacing of the preceding column. For example, if you specify:

```
-max_widths {,20,30}
```

The third column will have a maximum width of 20, the fourth column will have a maximum width of 30, and the first, second, and fifth columns will remain the default width spacing.

If you specify:

```
-max_widths {20,,30}
```

The first column will have a maximum width of 20, the third column will have a maximum width of 30, and the second, fourth and fifth columns will remain the default width spacing.

Each column resizes itself to be between the range of the maximum and minimum widths specified for that column, based on the data in that column. Overruns are wrapped within the same column, unless otherwise specified.

Default: {50,50,50,50,50}

<code>-min_widths integer</code>	Specifies the minimum width for each table column in the report specified by the <code>-name</code> parameter. Note: You cannot specify <code>-min_widths</code> parameter without <code>-name</code>. You can separate each specified width value with a comma (,). For example, if you specify: <pre>-min_widths {7,10,15}</pre> The first column will have a minimum width of 7, the second column will have a minimum width of 10, and the third column will have a minimum width of 15. The fourth and fifth columns will remain the default width spacing. Commas are also specified as column "placeholders", when you want to change the spacing of a column without changing the spacing of the preceding column. For example, if you specify: <pre>-min_widths {,,10,15}</pre> The third column will have a minimum width of 10, the fourth column will have a minimum width of 15, and the first, second, and fifth columns will remain the default width spacing. If you specify: <pre>-min_widths {7,,10}</pre> The first column will have a minimum width of 7, the third column will have a width of 10, and the second, fourth and fifth columns will remain the default width spacing. Each column resizes itself to be between the range of the maximum and minimum widths specified for that column, based on the data in that column. Overruns are wrapped within the same column, unless otherwise specified. Default: {5,5,5,5,5}
<code>-minor_sort integer</code>	Specifies the column to be used in the minor sort. It applies to <i>all</i> rows that have the same values in the <code>major_sort</code> column. If the column number is negative, the software reverses the sort.

<code>-name string</code>	Changes the formatting for the specified table. See Table for a list of table names you can use, and the commands with which they work.
<code>-no_frame_fix_width</code>	Specifies that the table columns have a fixed minimum width, but no maximum width (the data does not wrap). Column data that fits within the column's minimum width will left-justify and pad its location to fill the specified column space. Column data that is longer than the column's minimum width will take as much space in the table as needed. If a column is overwritten by the data from the preceding column, its data will begin on a new line at the correct column location. This is the default format for tables.
<code>-nosplit</code>	Specifies that each column follows the preceding column without splitting to a new line, if the data in one column overruns the next column. The wrapping behavior for data is controlled by the size of the display window. This format is useful for machine parsing the report. Note: You must specify <code>-no_frame_fix_width</code> in order to use this parameter.
<code>-reverse_rows</code>	Reverses the data rows. This is useful, for example, if you want to trace back from an end point and the default report traces forward from the end point.

The timing report formatting depends on the specified `set_table_style` parameters. These are described below:

- When `set_table_style -no_frame_fix_width` parameter is specified, the timing report displays long inst/hpin names and the rest of the column values are shown on the next line.
- When `set_table_style -no_frame_fix_width -nosplit` is specified, the timing report displays long inst/hpin names and rest of the column values are shown on the same line, because `-nosplit` table style is specified. In this case, other column headers (beyond inst/pin) may not be aligned properly.
- The following settings are specified:

```
set_table_style -no_frame_fix_width -nosplit
set_table_style -name report_timing -max_width {50,50,,,,,}
```

The generated report will show properly aligned column headers and end-point/begin-points are

not split.

- The following settings generate a report displaying longer (than above reports) inst/pin names:

```
set_table_style -no_frame_fix_width -nosplit  
set_table_style -name report_timing -max_width {120,120,,,,,}
```

In this report output, the column headers are aligned properly and are not split.

List of Table Names

Table Name	Formats Reports Generated by
report_cell_instance_delays_arcs	report_cell_instance_timing
report_cell_instance_delays_checks	report_cell_instance_timing
report_cell_instance_delays_pins	report_cell_instance_timing
report_inactive_arcs	report_inactive_arcs

report_timing_summary	report_timing

Examples

- The following command resizes the first column to a maximum range of 70 and specifies a default width of 50 for the second column. The default for the maximum width is 50 and the default for the minimum width is 5:

```
tempus> set_table_style -name report_timing -max_widths {70,}
```

Note: Do *not* include a blank space between commas "," when specifying widths. If you are specifying a value for the width(s), make sure there is *no* leading or trailing blank space.

- The following command specifies a default width of 50 for the first and second column:

```
tempus> set_table_style -name report_timing -max_widths {,}
```

- The following timing report shows the table style generated with the `no_frame_fix_width` parameter:

```
tempus> report_timing -format {cell arc delay arrival required instance}
```

```
Path 1: MET Setup Check with Pin seg3/u14/CK
Endpoint: seg3/u14/D (^) checked with leading edge of 'CLK3'
Beginpoint: seg3/u9/Q (^) triggered by leading edge of 'CLK3'
Path Groups: {CLK3}
Other End Arrival Time 0.621
- Setup 0.186
+ Phase Shift 2.000
= Required Time 2.434
- Arrival Time 2.062
= Slack Time 0.372
Clock Rise Edge 0.000
+ Clock Network Latency (Prop) 0.682
= Beginpoint Arrival Time 0.682
```

Cell	Arc	Delay	Arrival Time	Required Time	Instance
	CK ^		0.682	1.054	seg3/u9
DFF	CK ^ -> Q ^	0.185	0.867	1.240	seg3/u9

set_threshold_voltage_group

```
set_threshold_voltage_group  
[-help]  
[-hinst <string>]  
-name <group_name>  
[-override]  
{-libraries <library list> | -lib_cells <lib cell list>}
```

Groups timing libraries into different voltage threshold (Vth) classes (e.g., HVT, LVT, ULVT).

This command can be used to define (or redefine) the threshold voltage groups associated with the specified timing library cells. You can group entire libraries into a single group, or group by per library cell specification.

Parameters

-help	Prints out the command usage.
-hinst <string>	Specifies the hierarchical instances.
-lib_cells <lib cell list>	Specifies a list of library cells to be defined in the VT group.
-libraries <library list>	Specifies a list of libraries to be defined in the VT group.
-name <group_name>	Specifies the name of the threshold voltage group being defined.
-override	Allows you to override Liberty defined VT groups. If the Liberty timing library already has native <code>threshold_voltage_group</code> attributes at the library or library cell level, then you can use the -override parameter to customize it with the specified threshold voltage group.

Examples

- The following commands define library threshold voltage groups if they do not preexist in the .lib:

```
set_threshold_voltage_group -name SVT -libraries stdcell_vt_1p62V_cworst
set_threshold_voltage_group -name LVT -libraries stdcell_2vt_1p62V_cworst
set_threshold_voltage_group -name ULVT -libraries stdcell_vlvt_1p62V_cworst
set_threshold_voltage_group -name ELVT -libraries stdcell_flvt_1p62V_cworst
```

Related Commands

- `set_vt_skew_derate`
- `set_vt_skew_config`

Related Topics

For more information, refer to the "Voltage Threshold Skew Modeling and Analysis" section of [Analysis and Reporting](#) chapter in the *Tempus User Guide*.

set_timing_context_clock_mapping

```
set_timing_context_clock_mapping  
[-help]  
-block_clock block_clock_name  
[-instance string]  
-top_clock top_clock_name  
[-top_view view_name]  
[-view view_name]
```

Specifies user-defined clock mapping in context analysis. The auto-inferred clock mappings will be overridden by user-specified mappings. This command should not be specified directly in the Tempus shell.

Note: To ensure correct behavior, this command must be specified in the clock mapping file and subsequently loaded into the Tempus environment with the following command:

```
read_timing_context -clock_mapping_file clock_mapping_file
```

This command should not be run as a standalone command; it must be enclosed in the mapping file.

Parameters

-help	Prints out the command usage.
-block_clock <i>block_clock_name</i>	Specifies the name of the clock from the block-level analysis. The software maps the specified clock with the clock specified using the -top_clock parameter.
-instance <i>string</i>	Specifies the list of block instances for which the clock mapping is to be applied. When this parameter is not specified, the clock mapping is applied to all instances for which context analysis is to be performed.
-top_clock <i>top_clock_name</i>	Specifies the name of top level clock.
-top_view <i>view_name</i>	Specifies the name of the clock from top-level analysis. The software maps the specified clock with the clock specified using the -block_clock parameter.
-view <i>view_name</i>	Specifies the MMMC analysis view for which the top-block clock mapping is to be applied.

Examples

- In the following example, the block clock BCLK is mapped to top clock TCLK in block view B_view:

```
set_timing_context_clock_mapping -top_clock TCLK -block_clock BCLK -view B_view
```
- In the following example, the block clock BCLK is mapped to both top clocks TCLK1 and TCLK2 in

block view B_view:

```
set_timing_context_clock_mapping -block_clock BCLK -top_clock TCLK1 -view B_view
```

```
set_timing_context_clock_mapping -block_clock BCLK -top_clock TCLK2 -view B_view -add
```

- In the following example, the block clock BCLK is mapped only to TCLK2 in block view B_view:

```
set_timing_context_clock_mapping -block_clock BCLK -top_clock TCLK1 -view B_view
```

```
set_timing_context_clock_mapping -block_clock BCLK -top_clock TCLK2 -view B_view
```

Related Commands

set_timing_context_view_mapping

```
set_timing_context_view_mapping  
[-help]  
[-block_clock_suffix block_clock_suffix]  
-top_view topViewName  
-block_view blockViewName
```

Provides mapping between the top and block STA views. This command can be used only if the top and block STA view names differ.

A text file containing a set of `set_timing_context_view_mapping` commands can be provided to the `read_timing_context -view_map_file` parameter.

Parameters

<code>-help</code>	Prints out the command usage.
<code>- block_clock_suffix block_clock_suffix</code>	Specifies the suffix for block clock names. The block clocks with the specified suffix in the <code>block_view</code> name will only be mapped to the top clocks from the <code>top_view</code> .
<code>-block_view blockViewName</code>	Specifies the name of the view in the block-level analysis. The software maps the specified view with the <code>-top_view</code> view.
<code>-top_view topViewName</code>	Specifies the name of the view in the top-level analysis. The software maps the specified view with the <code>-block_view</code> view.

Examples

- The following example shows how a view mapping file can be setup:

```
set_timing_context_view_mapping -top_view T1_view -block_view B1_view  
set_timing_context_view_mapping -top_view T2_view -block_view B2_view
```

Related Commands

[-retain_delay]  
[-rise]  
[-sigma]  
[-static]  
[-statistical]  
[-transition]
```

Sets delay scaling or derating factors for early and late paths in the current design. You use this command to perform scaled on-chip variation around best-case and worst-case corners. The timing scaling factors affect the delay values generated in the timing reports. You can set scaling factors for data paths, clock paths, minimum and maximum operating conditions.

If you do not specify the `-clock` or `-data` parameter, the software applies the scaling factors to both clock and data paths. If you specify only one of the two parameters, `-data` or `-clock`, the software uses the last defined value for the other.

Similarly, if you do not specify the `-min` or `-max` parameter, the software applies the scaling factor to both minimum and maximum operating conditions. You should only use the `-min` or `-max` parameter for best-case worst-case analysis. If you specify them in on-chip variation (OCV) mode, the software will use the `-min -early` derating factor for early path scaling, and the `-max -late` derating factor for late path

adjustments.

When there are separate max and min libraries specified, only those `set_timing_derate` constraints are honored that are specified with max library. The constraints specified with min library are ignored.

In MMMC mode, for delay corners having different late and early library sets, only those `set_timing_derate` constraints are honored that are specified with late library set of the delay corner. The constraints specified with early library set are ignored.

Note: The `set_timing_derate` command can only be used on the command line. You cannot import it as part of an SDC file.

Note: If the `set_timing_derate` constraint is added incrementally in SI mode, an explicit `update_timing - full` command is required (before `report_timing` or `report_constraint`) for SI full accuracy.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-add</code>	Incrementally adds or subtracts derates. You can also apply derates on specific leaf instances. This parameter also support nets objects.
<code>-cell_check</code>	Specifies scaling on timing checks. Use the <code>-cell_check</code> option with the <code>-early</code> option to specify scaling on hold arcs and use with the <code>-late</code> option to specify scaling on setup arcs. When you specify this parameter, derating factors are also applied to user constraints such as <code>set_output_delay</code> , <code>set_data_check</code> , and <code>set_clock_gating_check</code> . The <code>-cell_check</code> parameter by default does not apply check derate to output external delay (e.g., <code>set_output_delay</code>). To enable this feature, you can set the <code>timing_apply_check_derate_to_external_output_delay</code> timing attribute to <code>true</code> . When set to <code>true</code> , this attribute applies cell derate to the top boundary port.
<code>-cell_delay</code>	Specifies scaling on cell delays. If neither the <code>-cell_delay</code> nor the <code>-net_delay</code> option is specified, the specified scaling factor applies to both types of delays.

<code>-clock</code>	Applies the derating factors to clock paths only.
<code>-clock_period_check</code>	Specifies derate values for clock period checks. Note: This parameter cannot be specified with the <code>-clock</code> , <code>-data</code> , <code>-cell_check</code> , <code>-cell_delay</code> , <code>-early</code> , <code>-retain_delay</code> , or <code>-net_delay</code> parameter.
<code>-corner</code>	Applies derating on cells or nets that are modeled as corner data elements. The specified derating factor is applied to both the mean and sensitivities of the delays (corner objects can have propagated sensitivities). A cell with no timing arc data in a library that has any sensitivity information with respect to any parameter defined in SPDF are considered as a corner object. All cells that do not qualify are considered to be statistical objects. A net with parasitic data that has no sensitivity information with respect to any parameter defined in SPDF is considered as a corner object. All nets that do not qualify are considered to be statistical objects.
<code>-data</code>	Applies the derating factors to data paths only.
<code>-delay_corner</code> <i>delayCornerName</i>	Applies the derating factor to the specified delay calculation corner or a list of delay corners. Note: The timing derate can be applied to corners associated with active views only.
<i>derate_value</i>	Specifies the derating value to be used.

`-dynamic`

Applies the specified derating factor to the delta portion of the net and cell delays. The delay typically models SI crosstalk adjustments from detailed RC analysis or annotation.

You can use this parameter in conjunction with the `-net_delay` or `-cell_delay` parameter to target the derate to desired components of the overall stage delay.

The delay calculation controls allow for the SI crosstalk impact to be apportioned to the cell delay and/or net delay. You should coordinate the use of `-dynamic` derate with your delay calculation configuration. For more information, you can refer to the following [si attributes](#):

- `si_delay_delta_annotation_mode`
- `si_delay_separate_on_data`

Notes

- To apply the derate with `-dynamic`, you must specify `si_delay_separate_on_data true` setting.
- When `-dynamic` is specified with:
 - `si_delay_delta_annotation_mode lumpedOnNet`, derate applies only to the SI component of net delays.
 - `si_delay_delta_annotation_mode arc`, derate applies to SI components of both cell and net delays.
 - `-cell_delay` parameter and `si_delay_delta_annotation_mode arc`, derate applies only to the SI component of cell delays.
 - `-net_delay`, the derate applies to the SI component of net delays.
- You cannot specify `-dynamic` with `-mean` or `-sigma` parameter.

<code>-early float</code>	Specifies that the derating factor applies to early paths. Early paths are launching clock during hold analysis, receiving clock during setup analysis and datapath during hold analysis. Note: To use this parameter, you must specify <code>-delay_corner</code>.
<code>-fall</code>	Applies the derating factor to falling delay and check arcs based on the transition direction at the arc's sink pin. This parameter can be used to selectively apply timing derates for the fall arcs (cell, net, or check arcs).
<code>-increment</code>	Incrementally adds the derate value to the total derate value in all the modes - OCV, AOCV, and SOCV mode. The <code>set_timing_derate</code> command saves two different values – the “base” derate and the “incremental” derate. When the <code>-incremental</code> parameter is specified, the software populates the incremental derates. Notes: • This parameter is used to specify incremental derates for leaf cell instances or library cell objects only. • <code>-increment</code> and <code>-multiply</code> are mutually exclusive parameters. • <code>-increment/-multiply</code> are supported with existing parameters, such as, <code>-late/-early</code>, <code>-rise/-fall</code>, <code>-mean/-sigma</code>. • Unlike base transition derate, the derate values with <code>-increment/-multiply</code> can be greater or smaller than 1. • Base transition derate values will be limited to: Late ≥ 1.0 and < 100.0, Early ≤ 1.0 and > 0.0. By default, a limit check on total derate value will be performed during transition for delay calculation. If the total transition derate is out of range, a warning

	message will be issued. By default, the incremental derates are overwritten. To disable this behavior, you can use the following global variables: • <code>timing_derate_incremental_adjust_additive_mode</code>: Incremental derates are added to each other to obtain the final incremental derate value. • <code>timing_derate_incremental_multiply_accumulative_mode</code>: Incremental derates are multiplied with each other to obtain the final incremental derate value. For more information, see timing category attributes. Note: The <code>-increment</code> parameter is mutually exclusive with <code>-pulse_width_check</code>, <code>-clock_period_check</code>, and <code>-input_switching</code> parameters.
<code>-input_switching</code>	Considers the given derate as simultaneous switching input (SSI) derate that is applicable to early paths only.
<code>-late float</code>	Specifies that the derating factor applies to late paths. Late paths are receiving clock during hold analysis, launching clock during setup analysis and data path during setup analysis. Note: To use this parameter, you must specify <code>-delay_corner</code>.
<code>-max</code>	Applies the derating factor to the maximum operating condition during best-case worst-case analysis. This parameter is ignored during on-chip variation analysis. Note: You cannot use the <code>-max</code> parameter when the software is in multi-mode multi-corner (MMMC) mode. You must use the <code>-delay_corner</code> parameter instead.

<code>-mean</code>	Controls nominal derating. You can apply separate derating the mean components of the delay. This parameter can be used in the SOCV analysis flow to specify a derating factor for the mean component of delays. For cell delays and checks, the <code>-mean</code> parameter is supported on library cell and instance objects. For net delays, it is supported as a global level derate factor. The <code>-multiply</code> and <code>-add</code> option can be used with the <code>-mean</code> parameter to provide an incremental adjustment to a previously specified mean base derate.
<code>-min</code>	Applies the derating factor to the minimum operating condition during best-case worst-case analysis. This parameter is ignored during on-chip variation analysis. Note: You cannot use the <code>-min</code> parameter when the software is in multi-mode multi-corner (MMMC) mode. You must use the <code>-delay_corner</code> parameter instead.
<code>-multiply</code>	Incrementally multiplies derates. You can also apply derates on specific leaf instances. This parameter also support nets objects.
<code>-net_delay</code>	Specifies scaling on net delays.
<code>object_list</code>	Specifies the list of instances, library cells, or nets to which the derating will be applied.
<code>-power_domain string</code>	Allows you to specify a specific power domain for the timing derate factors to be applied.
<code>-pulse_width_check</code>	Specifies derate values for pulse width checks. Note: The <code>-pulse_width_check</code> and <code>-clock_period_check</code> parameters are mutually exclusive. To apply check derating to pulse width checks, set the <code>timing_enable_derating_for_pulse_width_checks</code> attribute to <code>true</code>. By default, the attribute is set to <code>false</code>.

<code>-retain_delay</code>	Specifies scaling on retain constructs. If you specify both <code>-retain_delay</code> and <code>-cell_delay</code> parameters, the software uses the <code>retain_delay</code> value for retain construct scaling. If you do not specify the <code>-retain_delay</code> parameter, retain constructs are scaled in the same manner as cell delays. You cannot specify <code>-retain_delay</code> with <code>-mean</code> or <code>-sigma</code> parameters.
<code>-rise</code>	Applies the derating factor to rising delay and check arcs based on the transition direction at the arc's sink pin. This parameter can be used to selectively apply timing derates for the rise arcs (cell, net, or check arcs).
<code>-sigma</code>	Controls derating on the variation component. You can apply separate derating to the sigma components of the delay. This parameter can be used in the SOCV analysis flow to specify a derating factor for the variation component of delays. For cell delays and checks, the <code>-sigma</code> parameter is supported on library cell and instance objects. For net delays, it is supported as a global level derate factor. The <code>-multiply</code> and <code>-add</code> options can be used with the <code>-sigma</code> parameter to provide an incremental adjustment to a previously specified sigma base derate.
<code>-static</code>	Applies the specified derating factor to the non-delta portion of net delays only. You can specify <code>-net_delay</code> or <code>-cell_delay</code> parameter with the <code>-static</code> parameter. You cannot specify <code>-static</code> with <code>-mean</code> or <code>-sigma</code> parameters.

<code>-statistical</code>	Applies derating on cells or nets that are modeled as statistical data elements. The specified derating factor is applied to both the mean and sigma of delays. If both <code>set_timing_derate -corner</code> and <code>-statistical</code> options are not specified, the derating factor is applied on variation and corner objects equally. This is equivalent to issuing to two separate <code>set_timing_derate</code> commands, one with <code>-statistical</code> option and the other with <code>-corner</code> option.
<code>-transition</code>	Specifies scaling on transitions. When specified, the software allows derate transition and stretch waveforms. For incremental derates applied to the base derate (without the <code>-increment</code> parameter), you can use the following parameters with the <code>-transition</code> parameter: • <code>-increment</code> parameter adds to the base derate to obtain the final derate. • <code>-multiply</code> parameter multiplies the incremental derate with the base derate to obtain the final derate value (<code>-increment</code> parameter is not required). • Validity of final derate value (same limits as base transition derate) is applied only during timing analysis, and not at the time of constraint processing. Note: You can use the <code>-transition</code> parameter with the following parameters: • <code>-delay_corner</code> • <code>-early/-late</code> • <code>-rise/-fall</code> • <code>-mean/-sigma</code> • <code>-increment</code> • <code>-multiply</code>

Examples

- The following command (1) can be used when the software is in on-chip variation analysis mode to add pessimism to both the setup and hold analyses by making the early paths 20 percent faster:

```
set_db timing_analysis_type ocv
...
(1) set_timing_derate -early 0.8 -late 1.0
```

- The following example uses two `set_timing_derate` commands to set the scaling factors independently for the min and max corners. When the software is in best-case worst-case analysis mode:

- Command (1) adds pessimism to the setup analysis by making the latching clock path 20 percent faster.
- Command (2) adds pessimism to the hold analysis by making the latching clock path 10 percent slower.

```
(1) set_timing_derate -max -early 0.8 -late 1.0
(2) set_timing_derate -min -early 1.0 -late 1.1
```

- When the software is in on-chip variation analysis mode, there is only one active delay corner; therefore, the `-min` and `-max` parameters should not be used. The following command sequence will generate a warning:

```
set_db timing_analysis_type ocv
...
set_timing_derate -min -early 0.8 -late 0.9
set_timing_derate -max -early 1.1 -late 1.2
```

In this situation, the software uses 0.8 for derating early paths, and 1.2 for derating late paths.

- The following command sets the early path scaling factor of 0.85 for instance `MULT_9` cell delays:

```
set_timing_derate -early -cell_delay 0.85 [get_cells {MULT_9}]
```

- The following command sets the early path scaling factor of 0.75 for the net named `MUX2/Z`:

```
set_timing_derate -net_delay -early 0.75 [get_nets {MUX2/Z}]
```

- The following command specifies power domain `PD1` for derating instances:

```
set_timing_derate -power_domain PD1 -cell_delay 1.1
```

- In the following example, a design having max library as 'slow' and min library as 'fast', only the first two `set_timing_derate` constraints are honored:

```
set_timing_derate -late 1.2 [get_lib_cells {slow/BUFX1}] -cell_delay
set_timing_derate -early 0.8 [get_lib_cells {slow/BUFX1}] -cell_delay
set_timing_derate -late 1.1 [get_lib_cells {fast/BUFX1}] -cell_delay
```

```
set_timing_derate -early 0.9 [get_lib_cells {fast/BUFX1}] -cell_delay
```

- Consider the following library sets, in MMMC mode:

```
create_library_set -name libset1 -timing slow.lib
```

```
create_library_set -name libset2 -timing fast.lib
```

```
create_delay_corner -name corner1 -late_library_set libset1 -early_library_set libset2
```

From the following `set_timing_derate` constraints the first and last are honored:

```
set_timing_derate -late 1.2 -cell_delay [get_lib_cells slow/*] -delay_corner corner1
```

```
set_timing_derate -early 2.3 -cell_delay [get_lib_cells slow/*] -delay_corner corner1
```

```
set_timing_derate -late 3.4 -cell_delay [get_lib_cells fast/*] -delay_corner corner1
```

```
set_timing_derate -early 4.5 -cell_delay [get_lib_cells fast/*] -delay_corner corner1
```

- The following command can be used when the software is in on-chip variation analysis mode to add pessimism to both the setup and hold analyses by making the early paths 20 percent faster:

```
set_db timing_analysis_type ocv
```

```
...
```

```
set_timing_derate -early 0.8 -late 1.0
```

This command adds pessimism to the setup analysis by making the latching clock path 20 percent faster.

- The following example uses two `set_timing_derate` commands to set the scaling factors independently for the min and max corners. When the software is in best-case worst-case analysis mode:

- The following command sets the early path scaling factor of 0.85 for instance MULT_9 cell delays:

```
set_timing_derate -early -cell_delay 0.85 [get_cells {MULT_9}]
```

- The following command sets the early path scaling factor of 0.75 for the net named MUX2/Z:

```
set_timing_derate -net_delay -early 0.75 [get_nets {MUX2/Z}]
```

- The following command specifies power domain PD1 for derating instances:

```
set_timing_derate -power_domain PD1 -cell_delay 1.1
```

- The following command shows library object level support for clock (and pulse width) check options:

```
set_timing_derate -delay_corner -clock_period_check 1.05 [object_list]
```

- The following command sets an increment derate of 0.5 on mean and 0.8 on sigma of the cell:

```
set_timing_derate -increment 0.8 -sigma MP_32_INST/p11A
```

```
set_timing_derate -increment 0.5 -mean MP_32_INST/p11A
```

To increment the sigma derate further by 0.9, you can use the following command:

```
set_timing_derate -increment 0.9 -sigma MP_32_INST/p11A
```

The resultant sigma derate can be calculated as $1+0.9=1.9$.

When the `timing_derate_incremental_adjust_additive_mode` global variable is set to `true`, the resultant sigma derate will be $1+0.8+0.9=2.7$.

Related Commands

- `report_timing_derate`
- `reset_timing_derate`

set_timing_library

```
set_timing_library  
[-help]  
[-max {Max | Min}]  
[-min {Max | Min}]
```

Sets the timing libraries to be used in setup analysis (late-path delay calculation) or hold analysis (early-path delay calculation).

The default setting, if this command is not used, is that only maximum libraries will be used for setup analysis (late-path delay calculation) and only minimum libraries will be used for hold analysis (early-path delay calculation).

Use this command only after loading all the timing libraries.

Note: This command will become obsolete in the next major release as the software moves to using the Multi-Mode/Multi-Corner (MMMC) architecture for design import.

Parameters

-help	Prints out the command usage.
-max {Max Min}	Specifies the Max or Min libraries to be used in setup analysis.
-min {Max Min}	Specifies the Max or Min libraries to be used in hold analysis.

Examples

- The following command sets the timing library to `Max` used for both setup and hold analysis (early-path delay calculation):

```
tempus> set_timing_library -max Max -min Max
```
- The following script shows how to set a Min library in setup analysis and a Max library in hold analysis for reporting the detail data paths that do not meet timing in a report file:

```
tempus> set_timing_library -max Min -min Max  
tempus> set_db timing_analysis_check_type setup  
tempus> report_timing -max_points 10 > setupTiming.rpt  
tempus> set_db timing_analysis_check_type hold  
tempus> report_timing -max_points 10 > holdTiming.rpt
```
- The `set_timing_library -max Min -min Max` command sets the Min libraries for setup analysis and the Max libraries for hold analysis.

- The `set_db timing_analysis_check_type setup` command sets the timing analysis mode to `setup`.
- The `report_timing -max_points 10 > setupTiming.rpt` command runs `setup` analysis using the `Min Libraries` and writes the result to the `setupTiming.rpt` file.
- The `set_db timing_analysis_check_type hold` command sets the timing analysis mode to `hold`.
- The `report_timing -max_points 10 > holdTiming.rpt` command runs `hold` analysis using `Max Libraries` and writes the output to the `holdTiming.rpt` file.

set_vt_skew_config

```
set_vt_skew_config
[-help]
[-analysis_mode {setup | hold | both}]
[-clocks_only]
[-correlated_vt_groups <corr_group>]
[-exclude <exclude>]
[-exclude_nominal]
[-include_only <include_only>]
[-unique_vt_mode {none | slow | fast | nominal}]
```

Allows customization of the combinations of Vth classes to be analyzed. By default, the software will analyze all the possible combinations.

This command is not cumulative as each invocation will reset any options previously set by its default value unless that option is re-specified.

Parameters

-help	Prints out the command usage.
-analysis_mode {setup hold both}	Specifies the analysis mode for which the configuration is to be used.
-clocks_only	Allows the software to consider only launch and capture clock VTs post CPPR point when enumerating Vth combinations. By default, the software will consider Vth classes on the data path as well.
-correlated_vt_groups <corr_group>	Specifies the groups for correlation. By default, all Vth groups are considered uncorrelated. If a set of Vth groups is specified as correlated then they will be considered as one entity when determining the combinations of Vth groups. All the correlated VT's will use the same (fast, slow, nominal) derate factor.
-exclude <exclude>	Specifies the configurations to be excluded. When this parameter is specified, the software excludes some combinations of Vth classes from the full elaborated set of combinations. The argument to this parameter is a Tcl list-of-lists as described for <code>-include_only</code> . The <code>-exclude</code> expression is a secondary filter which acts against the the current included set of enumerations – either all by default, or a subset configured by <code>-include_only</code> .

<code>-exclude_nominal</code>	Determines whether to enumerate fast, slow, nominal combinations or just fast, slow.
<code>-include_only</code> <code><include_only></code>	Specifies the configurations to be included. You can specify only the Vth combinations of interest. By default, all the possible combinations are analyzed. The argument to this parameter is a Tcl list-of-lists structure, which associates a Vth group with the set of analyses to consider for that group. Note: The options for <code>-include_only</code> and <code>-exclude</code> parameters is a Tcl list-of-lists that provides a way to customize the Vth enumerations that are analyzed. The format is a Vth group name followed by an enum list of combinations of fast, slow, or nominal. If a Vth group is missing from the specification a value of 'all' will be assumed.
<code>-unique_vt_mode</code> {none slow fast nominal}	Allows the software to consider only the launch and capture clock VTs post CPPR point when enumerating Vth combinations. By default, the software will consider Vth classes on the data path as well. The unique Vt analysis mode is applicable only during the path-based analysis (PBA) step.

Examples

- The following command defines the derate mode to use in both GBA and PBA when the path has unique VT:

```
set_vt_skew_config -unique_vt_mode slow
```

Setting a unique Vt mode is required for the GBA unique Vt flow.

Related Commands

- `set_threshold_voltage_group`
- `set_vt_skew_derate`

Related Topics

set_vt_skew_derate

```
set_vt_skew_derate  
[-help]  
[-delay_corner <string>]  
[-fast <float>]  
[-hold]  
[-mean]  
[-setup]  
[-sigma]  
[-slow <float>]  
[-threshold_voltage_group <group name>]
```

Assigns fast and slow derate factors to specific threshold voltage groups.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-delay_corner <string></code>	Specifies the list of delay corners.
<code>-fast</code> <code><float></code>	Specifies the derate factor to use when evaluating both the early and late paths for a speed-up due to Vth skew shift. This derate value is expected to be less than 1.0.
<code>-hold</code>	Specifies that the derate is applied to the hold component.
<code>-mean</code>	Specifies that the derate is applied to the mean component. The specified derate only applies to mean delays in SOCV analysis. If the <code>-mean</code> or <code>-sigma</code> parameter is not specified, the derate applies to both the delay components.
<code>-setup</code>	Specifies that the derate is applied to the setup component.
<code>-</code> <code>sigma</code>	Specifies that the derate is applied to the sigma component. The specified derate only applies to the delay variation component in SOCV analysis.
<code>-slow <float></code>	Specifies the derate factor to use when evaluating both the early and late paths for a slow-down due to Vth skew shift. This derate value is expected to be greater than 1.0.
<code>-</code> <code>threshold_voltage_group</code> <code><group name></code>	Specifies the threshold voltage group that is either predefined in Liberty or defined using the <code>set_threshold_voltage_group</code> command.

Examples

- The following commands define the VT skew derate factors, and customize the different path combinations to be analyzed in PBA mode:

```
set_vt_skew_derate -threshold_voltage_group SVT -fast 0.90 -slow 1.10
set_vt_skew_derate -threshold_voltage_group LVT -fast 0.91 -slow 1.11
set_vt_skew_derate -threshold_voltage_group ULVT -fast 0.92 -slow 1.12
set_vt_skew_derate -threshold_voltage_group ELVT -fast 0.93 -slow 1.13
```

Related Commands

- `set_threshold_voltage_group`
- `set_vt_skew_config`

Related Topics

set_wire_load_mode

```
set_wire_load_mode
[-help]
mode
```

Controls how the software searches through the design hierarchy to find the appropriate wire load model for a net, or a hierarchical part of a net.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>set_wire_load_mode</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man set_wire_load_mode</code> .
mode	Specifies the wire-load model. You can specify one of the following options. - enclosed - segmented - top

	enclosed: Selects the wire load model using an area lookup table for the module that is at the lowest level in the design hierarchy and contains the entire net. When you set the mode to <code>enclosed</code>, the software uses the area of the smallest block enclosing the net to select the wire load model. In the <code>enclosed</code> mode, the software uses the following order of precedence to search the wire load model in: • The inner-most block enclosing the net on which you set the wire load selection group using the <code>set_wire_load_selection_group</code> command, if the <code>auto_wire_load_selection</code> global variable is enabled. Or: The inner-most block enclosing the net on which you set the wire load model using the <code>set_wire_load_model</code> command. • Each higher level hierarchical block for a <code>set_wire_load_selection_group</code> assertion, all the way up to the top-level block, if the <code>auto_wire_load_selection</code> global variable is enabled. Or: Each higher level hierarchical block for a <code>set_wire_load_model</code> assertion, all the way up to the top-level block. • The <code>default_wire_load_selection</code> field in the first timing library. Or, The <code>default_wire_load</code> field in the first timing library. Note: If even the default values are not present in the timing library, you will not be able to use the wireload model functionality.
	segmented: Selects the wire load model in a way similar to the <code>enclosed</code> mode except that each hierarchical segment of the net is treated separately. In the <code>segmented</code> mode: • A segment is defined by pins (including hierarchical pins) connected to a particular net. • When counting the drivers and receivers, only the pins connected to the segment are considered. This information along with the wire load models determine the parasitic information for the segment. • The parasitics of each segment sum up to form the parasitics for the entire net. Note: Each segment may have different wire load models.

`top`: Selects the wire load model in a way similar to `enclosed` and `segmented` except that all nets use the wire load selection or wire load models defined by the top-level (largest) block enclosing the net.

Note: If the first library read in does not define the default wire load mode, the software uses `top` as the default mode.

Examples

- The following command sets the wire load mode to `enclosed`:

```
tempus > set_wire_load_mode enclosed
```

Related Commands

- `reset_wire_load_mode`

set_wire_load_model

```
set_wire_load_model  
[-help]  
[obj_list]  
[-library library_name]  
[-max]  
[-min]  
-name wireload_model
```

Specifies the wire load model to be used from the technology library, and sets the wire load model on the design or on a hierarchical object (instance). If the list of instances is not specified, the wire load model is set on the current instance. Otherwise, the wire load model is set on all the specified instances or ports.

Use wire load models for estimating delays before the actual wire loads are back annotated. A technology library contains different wire load models, previously computed based on the analysis of several designs differing in area.

Parameters

-help	Prints out the command usage.
-library library_name	Specifies the technology library to use when searching for the name of the wire load model. You can specify a library name, or a collection of libraries. <i>Default:</i> All technology libraries are searched.
obj_list	Specifies the list of objects - designs, ports, or hierarchical instances.
-max	Sets the wire load model only for the maximum PVT (process, voltage, temperature) corner. <i>Default:</i> The specified wire load model applies to all three PVT corners if neither the -min nor the -max parameter is specified.
-min	Sets the wire load model only for the minimum PVT (process, voltage, temperature) corner. <i>Default:</i> The specified wire load model applies to all three PVT corners if neither the -min nor the -max parameter is specified.
-name wireload_model	Specifies the name of the wire load model in the library.

Examples

- The following command sets the `COM3_LV_WLM_0.0` wire load model from the `COM3_LV_WIRE` library on the current module for all PVT corners:

```
tempus> set_wire_load_model -library COM3_LV_WIRE -name COM3_LV_WLM_0.0
```
- The following command sets the `B1X1` wire load from the `lca500kv` library on the `clk1` port for the minimum PVT corner:

```
tempus> set_wire_load_model -library lca500kv -min -name B1X1 clk1
```
- The following command sets the `3M_TO_4500K` wire load from the `c13tsmc_slow2s108v125c` library on the current module for the minimum PVT corner:

```
tempus> set_wire_load_model -library c13tsmc_slow2s108v125c -min -name 3M_TO_4500K
```

Related Commands

- `report_wire_load`
- `reset_wire_load_model`

set_wire_load_selection_group

```
set_wire_load_selection_group  
[-help]  
group_name  
[hinst_list]  
[-library library_name]  
[-max]  
[-min]
```

Overrides the wire load selection table in the specified library.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>set_wire_load_selection_group</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man set_wire_load_selection_group</code>
group_name	Specifies the name of the wire load selection group.
-library library_name	Specifies the name of the technology library to search for the wire load selection table. When this parameter is not specified, the software searches all the libraries.
hinst_list	Specifies the list of instances.
-max	Controls the choice of a wire load selection table only for the PVT max corner. <i>Default:</i> Selects the table for all PVT corners if neither the <code>-min</code> nor the <code>-max</code> parameter is specified.
-min	Controls the choice of a wire load selection table only for the minimum PVT corner. <i>Default:</i> Selects the table for all PVT corners if neither the <code>-min</code> nor the <code>-max</code> parameter is specified.

Examples

- The following command selects `TLM` as the selection table used by the library:
`set_wire_load_selection_group TLM`
- The following command selects `ASPEC1` as the selection table used by the `sm333s` library; only the minimum PVT corner is affected:
`set_wire_load_selection_group -min -library sm333s ASPEC1`

Related Commands

- `reset_wire_load_selection_group`

timing_enable_boundary_model_eco

timing_enable_boundary_model_eco
[-help]

Enables all the boundary model settings that are required to be set for proper working of the ECO flow.

This command should be used after all the STA settings have been made. You can use this command in the `create_boundary_model` and `read_boundary_model` command sessions.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

Related Commands

- `create_boundary_model`
- `read_boundary_model`

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `check_drc` category, use the following command:

```
get_db -category check_drc
```

timing_all_registers_filter_clock_pins_by_clock

```
timing_all_registers_filter_clock_pins_by_clock {true | false}
```

Default: `false`

Data_type: Boolean

Reports clock pins filtered based on specified clocks.

When set to `true`, the software will filter and return only those clock pins where at least one clock is from the specified list of clocks.

This attribute applies only when any of the `all_registers` command parameters, `-clock`, `-rise_clock`, `-`

`fall_clock`, is specified.

timing_all_registers_identify_macros_include_is_macro_cell

```
timing_all_registers_identify_macros_include_is_macro_cell {true | false}
```

Default: `true`

Data_type: Boolean

Enables to include cells as macro cells.

When set to `true`, the software includes cells as macro cells if the `is_macro_cell` property (see [get_property](#)) is set to `true` in the library.

When set to `false`, the `all_registers` command will not return cells for which the `is_macro_cell` property is `true`.

timing_all_registers_include_icg_cells

```
timing_all_registers_include_icg_cells {true | false}
```

Default: `true`

Data_type: Boolean

Includes integrated clock gating (ICG) cell information from the `all_registers` report output.

When set to `false`, the attribute does not allow the `all_registers` command report output to display ICG cell details.

timing_allow_input_delay_on_clock_source

```
timing_allow_input_delay_on_clock_source {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, this attribute allows the software to apply input delay constraints on a pin where a clock was previously asserted.

timing_analysis_aocv

```
timing_analysis_aocv {true | false}
```

Default: false

Data_type: Boolean

Sets the analysis mode to advanced on-chip variation (AOCV) analysis.

timing_analysis_aging

```
timing_analysis_aging {true | false}
```

Default: false

Data_type: Boolean

Enables timing-aware aging analysis.

The aging feature must be enabled before the timing updates are done.

Note: You cannot disable this feature in the same session later.

timing_analysis_async_checks

```
timing_analysis_async_checks {async | no_async | async_only | auto}
```

Default: auto

Data_type: Enum

Reports timing violations for asynchronous timing checks, including recovery and removal, and other checks on pins defined as preset or clear in the Liberty file.

The following options are supported:

- **async:** Reports timing checks on pins that are defined as preset or clear in the Liberty file.
- **no_async:** Reports timing violations while ignoring the two time arc attributes.
- **async_only:** Reports only recovery and removal checks.

The following setting corresponds to `set timing_disable_recovery_removal_checks true` in Tempus legacy.

```
set_db timing_analysis_async_checks no_async
```

The following setting corresponds to `set timing_disable_recovery_removal_checks false` in Tempus legacy.

```
set_db timing_analysis_async_checks async
```

timing_analysis_check_type

```
timing_analysis_check_type {setup | hold}
```

Default: setup

Data_type: Enum

Checks the design for setup or hold violations in the current analysis.

Note: When simultaneous setup/hold mode analysis is on, this setting does not have any impact. You can use the `report_timing -late/-early` parameter to report setup/hold timing reports.

timing_analysis_clock_gating

```
timing_analysis_clock_gating {true | false}
```

Default: true

Data_type: Boolean

Enables clock gating checks.

timing_analysis_clock_propagation_mode

```
timing_analysis_clock_propagation_mode {sdc_control | forced_ideal}
```

Default: sdc_control

Data_type: Enum

Specifies how to determine whether clock end points are interpreted as having either ideal or propagated clock timing.

- `sdc_control`: Reports the timing violations considering clock tree and enables propagating clocks to report clock latency. You must set the `set_propagated_clock` constraint to propagate the clocks.
Note: By default, CTS will instruct the timer to make all of the clock roots propagated. In this case, you do not need to set the `set_propagated_clock` constraint.

- `forced_ideal`: Does not report the timing violations considering the clock tree.

timing_analysis_clock_source_paths

`timing_analysis_clock_source_paths {true | false}`

Default: `true`

Data_type: Boolean

Reports combinational paths from the clock source to the timing checks on data pins.

When set to `false`, the clock portion of the path is considered as ideal (due to the SDC constraints or the `timing_analysis_clock_propagation_mode forced_ideal` attribute setting), the delay calculation software treats the clock nets as ideal nets when calculating the delays and slews along the data path.

timing_analysis_cppr

`timing_analysis_cppr {both | none | setup | hold}`

Default: `none`

Data_type: Enum

Removes pessimism from clock paths that have a portion of the clock network in common between the clock source and clock destination paths.

The pessimism is introduced when the timing analysis tools assume that the common path has different delay values for two different paths in case of on-chip variation. The pessimism can also be because of clock reconvergence in the clock network. The pessimism effects all analysis modes including single, best case-worst case (bcwc), and on-chip variation.

- `none`: Disables removal of clock reconvergence pessimism.
- `both`: Enables removal of clock reconvergence pessimism for both setup and hold modes.
- `setup`: Enables removal of clock reconvergence pessimism in setup mode only.
- `hold`: Enables removal of clock reconvergence pessimism in hold mode only.

timing_analysis_engine

`timing_analysis_engine {statistical | static}`

Default: `static`

Data_type: Enum

Allows you to specify the analysis engine - Statistical or Static - for performing timing analysis.

timing_analysis_enable_inter_power_domain

```
timing_analysis_enable_inter_power_domain {true | false}
```

Default: `false`

Data_type: Boolean

Enables IPD analysis.

For more information, refer to the [Inter Power Domain \(IPD\) Analysis](#) chapter in the *Tempus Stylus User Guide*.

timing_analysis_enable_robustness_mode

```
timing_analysis_enable_robustness_mode {true | false}
```

Default: `false`

Data_type: Boolean

Enables PTR analysis.

The Parametric Timing Robustness (PTR) analysis calculates the probability of an entire chip meeting timing requirements, instead of relying on the probabilities on individual paths to compute the robustness of a chip.

timing_analysis_graph_pba_mode

```
timing_analysis_graph_pba_mode {true | false}
```

Default: `false`

Data_type: Boolean

When specified, the software performs partial PBA analysis during GBA to reduce GBA pessimism.

timing_analysis_multi_input_switching_mode

```
timing_analysis_multi_input_switching_mode int
```

Default: 0

Data_type: Integer

Sets the multiple-input switching (MIS) mode.

You can specify one of the following options below:

- 0: Simultaneous input switching is not considered.
- 1: MIS analysis considers cells for which multiple inputs of a cell are tied together (tied-inputs).
- 2: MIS analysis considers both the tied-inputs and inputs of cells switching independent to each other.
- 3: Enables derate-based MIS. When MIS-derate is enabled, Tempus will automatically disable AMIS-simulation.

timing_analysis_precision_ps

```
timing_analysis_precision_ps {0.1 | 0.01}
```

Default: 0.01

Data_type: Double

Allows you to set the delay precision value (in 0.1ps or 0.01ps) for the `write_sdf` command.

The `write_sdf` command shows a double digit value after the decimal point by default. You can use this attribute for more accuracy.

timing_analysis_self_loops_paths_no_skew

```
timing_analysis_self_loops_paths_no_skew {true | false}
```

Default: false

Data_type: Boolean

Checks for self loop paths without skew.

When set to `true`, the software eliminates clock skew due to clock uncertainty for a path starting and ending at the same register. If the clock skew is not eliminated, the timing for such paths is pessimistic.

timing_analysis_socv

```
timing_analysis_socv {true | false}
```

Default: false

Data_type: Boolean

Enables SOCV Analysis.

timing_analysis_type

```
timing_analysis_type {single | best_case_worst_case | ocv}
```

Default: ocv

Data_type: Enum

Sets the timing analysis type to single, best case worst case or on-chip variation.

In this mode, the software calculates the delay for one path based on maximum operating condition while calculating the delay for another path based on minimum operating condition for setup or hold checks.

- `single`: Scales the delay values based on one operating condition.
- `best_case_worst_case`: Checks the design for two extreme operating conditions. The software uses the maximum delays for all paths during setup checks and minimum delays for all paths during hold checks.
- `ocv`: Calculates the delay for one path based on maximum operating condition while calculating the delay for another path based on minimum operating condition for setup or hold checks.

If you read in one library set and do not specify any timing analysis type, the software uses `single` by default. If you read in two library sets and do not specify any timing analysis type, the software uses `best_case_worst_case` by default.

For more information, see [Timing Analysis Modes](#) in the *Tempus User Guide*.

timing_aocv_analysis_mode

```
timing_aocv_analysis_mode {launch_capture | clock_only | separate_data_clock |  
combine_launch_capture}
```

Default: launch_capture

Data_type: Enum

Controls handling of AOCV analysis modes.

- **launch_capture**: AOCV analysis will be performed for both data and clock paths, and the AOCV derating factor will be calculated based on both clock and data path stages.
- **clock_only**: AOCV analysis will be performed for clock paths only, and the AOCV derating factor will be calculated based on the clock path stage depth only.
- **separate_data_clock**: The software calculates the AOCV stage count for clock paths and data paths separately. Both clock and data paths have related AOCV derating factors.
- **combine_launch_capture**: The software calculates AOCV stage count using combined depth for launch and capture paths. This is achieved by summation of path depth on the launch and capture paths.

timing_aocv_chip_size

`timing_aocv_chip_size double`

Default: 1e+30

Data_type: double

Specifies the diagonal length of the chip, in microns. The software will automatically calculate the length from the SPEF file, if it is loaded.

The chip and core sizes specified with the `timing_aocv_chip_size` and `timing_aocv_core_size` attributes take priority over chip and core size values derived from the SPEF file, or through placement. When the SPEF file is not loaded, or placement information is not available, then the following cases are considered:

- If you specify `timing_aocv_chip_size` but not `timing_aocv_core_size`, the software considers the core size to be equal to the `timing_aocv_chip_size` value.
- If you specify `timing_aocv_core_size` but not `timing_aocv_chip_size`, the software ends the AOCV analysis and generates an error message.
- If both `timing_aocv_chip_size` and `timing_aocv_core_size` are not specified, the software ends the AOCV analysis and generates an error message.

timing_aocv_core_size

`timing_aocv_core_size real_number`

Default: 1e+30

Data_type: double

Specifies the diagonal length of the core area, in microns. The software will automatically calculate the length from the SPEF file, if it is loaded.

The chip and core sizes specified with the `timing_aocv_chip_size` and `timing_aocv_core_size` attributes take priority over chip and core size values derived from the SPEF file, or through placement. When the SPEF file is not loaded, or placement information is not available, then the following cases are considered:

- If you specify `timing_aocv_chip_size` but not `timing_aocv_core_size`, the software considers the core size to be equal to the `timing_aocv_chip_size` value.
- If you specify `timing_aocv_core_size` but not `timing_aocv_chip_size`, the software ends the AOCV analysis and generates an error message.
- If both `timing_aocv_chip_size` and `timing_aocv_core_size` are not specified, the software ends the AOCV analysis and generates an error message.

timing_aocv_derate_mode

```
timing_aocv_derate_mode {aocv_multiplicative | aocv_additive}
```

Default: aocv_multiplicative

Data_type: Enum

Controls the AOCV derating mode.

When set to `aocv_multiplicative`, the derating factor will be calculated as AOCV derating * OCV derating, which is set using the `set_timing_derate` command.

When set to `aocv_additive`, the derating factor will be calculated as AOCV derating + OCV derating values.

When you use this attribute, the `report_timing` command shows the `total_derate` column in the timing report output, which allows you to view and cross-check the calculated total derate factor.

timing_aocv_stage_count_update_on_timing_reset

```
timing_aocv_stage_count_update_on_timing_reset {true | false}
```

Default: false

Data_type: Boolean

When set to true, the AOCV stage counts are re-calculated when timing is reset.

timing_apply_check_derate_to_external_output_delay

```
timing_apply_check_derate_to_external_output_delay {true | false}
```

Default: false

Data_type: Boolean

Applies check derate to output external delay.

The `set_timing_derate -cell_check` parameter by default does not apply check derate to output external delay (using the `set_output_delay` command). To enable this feature, you can set the `timing_apply_check_derate_to_external_output_delay` timing attribute to `true`. The attribute applies cell (check) derate to the top boundary port.

timing_apply_default_primary_input_assertion

```
timing_apply_default_primary_input_assertion {true | false}
```

Default: true

Data_type: Boolean

When set to `true`, primary input and bidirectional ports that do not have an explicit arrival time specified (through the `set_input_delay` constraint), are provided a default arrival time. The arrival is referenced to an internal default clock that is indicated by the `@` sign in various timing reports.

If a `set_input_delay` constraint is assigned to the input port, but the `-clock` parameter was not specified, the software assumes the constraint to be with reference to the default clock.

When set to `false`, inputs ports with no explicit `set_input_delay` are unconstrained for sequential timing analysis.

timing_apply_exceptions_to_data_check_related_pin

```
timing_apply_exceptions_to_data_check_related_pin {true | false}
```

Default: true

Data_type: Boolean

Controls if false path assertions which block the data path to the related (-from) reference pin of the

data-to-data check disable the data-to-data check.

When set to `false`, the data-to-data remains valid when a false path assertion blocks the data path to the related (-from) pin.

When set to `true`, any false path assertion which blocks the data path to the related (-from) pin of the data-to-data check also causes the check to be disabled.

This attribute has no effect on the data-to-data checks with a reference clock, where an exception blocks the clock reference signal at the reference pin. The data-to-data check will always be disabled in this situation.

Examples

- In the following example, the data-to-data check is disabled:

```
set timing_apply_exceptions_to_data_check_related_pin true
set_data_check -from portA -to portB
set_false_path -to portA
```

- In the following example, the data-to-data check is valid. This is the default situation:

```
set timing_apply_exceptions_to_data_check_related_pin false
set_data_check -from portA -to portB
set_false_path -to portA
```

- In this case, the data check is always disabled and is not affected by this attributes' settings:

```
set_data_check -from portA -to portB
set_false_path -to [get_clocks ClkA]
```

where the path to `portA` is clocked by `ClkA`.

timing_apply_setup_hold_exceptions_to_data_check_related_pin

```
timing_apply_setup_hold_exceptions_to_data_check_related_pin {true | false}
```

Default: `true`

Data_type: Boolean

Disables the early signal data-to-data paths, when false path is applied on the late reference path.

When set to `true`, the `set_false_path -setup` parameter settings on the reference path disables early signal d2d path, and vice versa. If both the `-setup` and `-hold` parameters are set, the signal early/late d2d path is disabled, irrespective of this attribute's settings.

When set to `false`, the `set_false_path` exceptions set on d2d reference path do not affect data path slack. When the `set_false_path` command is set on the reference d2d path with only `-setup` (or only `-hold`) parameter, the signal path of d2d check is not affected by these exceptions.

timing_cap_unit

`timing_cap_unit string`

Default: " "

Data_type: string

Specifies the capacitance units to be used for timing constraints and timing reports. The default unit for capacitance is inferred from the timing libraries. You can override this inference by explicitly setting the value to 1pf or 1ff. Setting this variable explicitly is the same as executing the `set_library_unit - cap` command to set the capacitance units.

timing_case_analysis_for_icg_propagation

`timing_case_analysis_for_icg_propagation {false | require_seq_prop | always | case_only | constant_only}`

Default: false

Data_type: Enum

Controls whether constants, which propagate to the inputs of integrated clock gating (ICG) cells, are further propagated to the output pins of these cells. The ICG cells typically contain an internal register or latch structure which synchronizes the devices' enable signal. If a constant propagates to this enable, it can be selectively propagated through the internal sequential element to the related output pins.

This attribute setting can uniquely control the handling of sequential propagation through ICG cells, or it can work in conjunction with the more general `timing_case_analysis_for_sequential_propagation` attribute settings.

The constants can be present in the analysis due to several different reasons, broadly breaking down to netlist constants and case analysis. The netlist constants come from connections to tie-hi or tie-lo cells, a 1'b0/1'b1 assignment in the netlist, or explicit power rail connections. The constants derived from these sources are considered to be immutable. The constants due to case analysis come strictly from the `set_case_analysis` constraint and are considered to be temporary - configuring the analysis to align to a certain mode. You may choose to handle constants from any source in a similar manner or customize the handling based on the constant type.

If you choose to allow propagation of only a specific type of constant, the output pin's state function must resolve to a constant by only considering inputs pins with the required constant type. Otherwise, the constant will not be propagated.

The propagation of constants to the output of a sequential device may affect how the timing checks on related input pins are analyzed. If all the possible transitions on a given input pin are unable to change the constant state of the output pin, the timing checks on the input pin will be disabled by default.

Changing the state of this attribute will change where constants are present in the analysis, typically resulting in sets of timing arcs and timing checks being enabled or disabled. As a result, a full timing update, including a fresh delay calculation, will be initiated when this setting is toggled.

You can use one of the following options:

Option	Description
false	Disables sequential propagation from any constant source (default setting).
require_seq_prop	When specified, the software will defer ICG sequential propagation handling to what is more generally set for all sequential devices, via either the <code>timing_case_analysis_for_sequential_propagation</code> attribute setting. For all the other options, the state of these external settings is not consequential.
always	Allows sequential propagation from any constant source - netlist or constraint-based.
constant_only	Allows sequential propagation only for constants that are due to the propagation of netlist-based constants.
case_only	Allows sequential propagation only for constants that are due to the propagation of constraint-based constants from <code>set_case_analysis</code> settings.

timing_case_analysis_for_sequential_propagation

`timing_case_analysis_for_sequential_propagation {false | true | case_only | constant_only}`

Default: false

Data_type: Enum

Controls whether constants, which propagate to the inputs of sequential devices like registers or flip-flops, are propagated to the output pins of those devices. This attribute will also affect the propagation of constants through integrated clock gating (ICG) cells - depending on the setting of the related attribute `timing_case_analysis_for_icg_propagation`. Refer to the documentation for this attribute for more information on ICG handling.

The constants can be present in the analysis due to several different reasons - broadly breaking down to netlist constants and case analysis. The netlist constants come from connections to tie-hi or tie-lo cells, a 1'b0/1'b1 assignment in the netlist, or explicit power rail connections. The constants derived from these sources are considered to be immutable. The constants due to case analysis come strictly from the `set_case_analysis` constraint and are considered to be temporary - configuring the analysis to align to a certain mode. You may choose to handle constants from any source in a similar manner or customize the handling based on the constant type.

If you choose to allow propagation of only a specific type of constant, the output pin's state function must resolve to a constant by only considering inputs pins with the required constant type. Otherwise, the constant will not be propagated. The propagation of constants to the output of a sequential device may affect how the timing checks on related input pins are analyzed. If all the possible transitions on a given input pin are unable to change the constant state of the output pin, the timing checks on the input pin will be disabled by default.

Changing the state of this attribute will change where constants are present in the analysis, typically resulting in sets of timing arcs and timing checks being enabled or disabled. As a result, a full timing update, including a fresh delay calculation, will be initiated when this setting is toggled. You can use one of the following options:

Option	Description
false	Disables sequential propagation from any constant source (default setting).
true	Allows sequential propagation from any constant source - netlist or constraint-based.
constant_only	Allows sequential propagation only for constants that are due to the propagation of netlist-based constants.
case_only	Allows sequential propagation only for constants that are due to the propagation of constraint-based constants from the <code>set_case_analysis</code> command.

timing_case_analysis_propagation

```
timing_case_analysis_propagation {true | false}
```

Default: true

Data_type: Boolean

Enables case analysis propagation.

The `timing_case_analysis_propagation` attribute is the top-level control for enabling or disabling all case propagation in the current session. When set to `true`, case propagation will be enabled and other attributes can then be used to selectively control case propagation in specific circumstances. The `timing_case_analysis_for_sequential_propagation` attribute variable can be used to control whether case is propagated across sequential devices. Propagation through integrated clock-gating (ICG) cells can be controlled with the `timing_case_analysis_for_icg_propagation` attribute.

When set to `false`, the software disables case analysis propagation.

timing_check_timing_report_all_checks

timing_check_timing_report_all_checks {true | false}

Default: false

Data_type: Boolean

Enables reporting of all the checks performed by the `check_timing` command.

When set to `true`, the `check_timing` command reports all the checks performed, even if there is no violation(s) for the corresponding check type.

When set to `false`, only the check types that have any violations will be reported.

timing_check_timing_signal_level_high_to_low_threshold

timing_check_timing_signal_level_high_to_low_threshold *double*

Default: 0.0

Data_type: Double

Sets the threshold value for warning the signal level difference between driver and receiver voltages, when the driver is at a higher voltage than the receiver voltage.

The software shows the signal level warnings (`check_timing signal_level`) that report the net driver/receiver pin pairs for which the pin voltage does not match. The signal level warning messages can be filtered based on these threshold values.

timing_check_timing_signal_level_low_to_high_threshold

timing_check_timing_signal_level_low_to_high_threshold *double*

Default: 0.0

Data_type: Double

Sets the threshold value for warning the signal level difference between driver and receiver voltages, when the driver is at a lower voltage than the receiver voltage.

The software shows the signal level warnings (`check_timing signal_level`) that report the net driver/receiver pin pairs for which the pin voltage does not match. The signal level warning messages can be filtered based on these threshold values.

timing_clock_phase_propagation

`timing_clock_phase_propagation {positive | negative | both}`

Default: both

Data_type: Enum

Allows you select the appropriate clock phases at register clock pins when both positive and negative phases of the same clock signal are seen in the clock network. For example, a register whose clock pin is fed by a two-input XOR gate where one input is a clock port and the other input is a data port. When the value of the data signal of the XOR gate is unknown, the XOR gate can see both positive and negative phases of the clock signal.

both	Selects both positive and negative clock phases at the register clock pins.
positive	Selects positive clock phases.
negative	Selects negative clock phases.

timing_clock_source_paths_unconstrained_mark_clock_used_as_data

`timing_clock_source_paths_unconstrained_mark_clock_used_as_data {true | false}`

Default: true

Data_type: Boolean

The `is_clock_used_as_data` property (by using the `get_property` command) returns a value of `true` for unconstrained clock source network.

timing_clock_source_use_driving_cell

`timing_clock_source_use_driving_cell {true | false}`

Default: true

Data_type: Boolean

When set to `false`, delay calculation in propagated clock mode will use an idealized driver model at the `create_clock` root pin or port when it calculates delays for the first stage of the clock tree. The idealized model is a ramp input with the transition time set by the system default transition, which is normally 0ns.

When this variable is set to `true`, the drive characteristics of the cell output pin that `create_clock` is asserted on will be used to calculate the first stage clock tree delays and slews. The input slew used for this driver model is whatever slew has been propagated to the cell's input pins from upstream logic. The arrival time of the clock at the root pin is not modified in any way.

If you wish to specify the input slews to be used for the clock driver cell, that is, not use the upstream propagated slews - you can use the `set_annotated_transition` constraint on the cell's input pins to control this. Setting an input transition of 0ns on the input pins can be useful when trying to correlate analysis results with other applications which do not use the full propagated transition times.

timing_clock_uncertainty_from_to_precedence

```
timing_clock_uncertainty_from_to_precedence {true | false}
```

Default: `false`

Data_type: Boolean

Sets the clock uncertainty precedence.

When set to `true`, the software gives higher precedence to clock-to-clock uncertainty.

timing_collection_all_fanin_fanout_traversal_mode

```
timing_collection_all_fanin_fanout_traversal_mode {hierarchical | flat}
```

Default: `flat`

Data_type: Enum

Controls how the software processes netlists during `all_fanin/all_fanout` command processing.

timing_collection_result_display_limit

```
timing_collection_result_display_limit integer
```

Default: `100`

Limits the number of objects of a collection to be displayed in the output report.

When set to an integer value, all the commands, such as, `get_cells`, `add_to_collection`, and `query_objects` commands, that display collection objects in the output report will be impacted.

When set to `-1`, all the elements in the collection will be displayed in the output.

timing_collection_variable_assignment_compatibility

```
timing_collection_variable_assignment_compatibility {true | false}
```

Default: true

Data_type: Boolean

Disables printing the names of the output of `get_*` commands.

When set to `false`, the software prints the `get_*` command output on the shell. This attribute should be used for debugging purposes only.

timing_context_apply_default_primary_input_assertion

```
timing_context_apply_default_primary_input_assertion {true | false}
```

Default: false

Data_type: Boolean

Propagates the phase at block level for unmapped clocks.

When set to `true`, the nets in the fanout of data ports with unmapped clocks are considered to have infinite timing windows during SI context analysis.

When set to `false`, the unmapped top clock arrivals on data ports are dropped during context analysis.

timing_context_apply_port_sdc_exceptions

```
timing_context_apply_port_sdc_exceptions {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software will consider path exceptions on block constraints in the hierarchical context flow.

timing_context_clock_mapping_percentage_tolerance

```
timing_context_clock_mapping_percentage_tolerance double
```

Default: 0.0

Data_type: Double

Controls the tolerance value of period and waveform in clock mapping.

timing_context_clock_mapping_check_waveform

```
timing_context_clock_mapping_check_waveform {true | false}
```

Default: true

Data_type: Boolean

Controls the waveform checking.

timing_context_continue_on_invalid_module_list

```
timing_context_continue_on_invalid_module_list {true | false}
```

Default: false

Data_type: Boolean

Enables to continue timing analysis without generating timing context.

When set to `true`, the software will continue with timing analysis without generating timing context, when all the specified modules/instances are invalid.

timing_context_clock_phase_based_clock_mapping

```
timing_context_clock_phase_based_clock_mapping  
{true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the port-based clock mapping search is enhanced by additionally attempting to map originally unmapped top clocks.

Such unmapped top clock on data port is to be mapped to block clock if top clock was mapped to block clock as a clock on clock port.

Note: This attribute can be used when `timing_context_port_based_clock_mapping` is set to `true`.

timing_context_data_phase_based_clock_mapping

```
timing_context_data_phase_based_clock_mapping {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the port-based clock mapping search () is enhanced by additionally trying to map originally unmapped top clocks.

Such unmapped top clock on data port is to be mapped to block clock if top clock was mapped to block clock on other data ports.

Note: This attribute can be applied when `timing_context_port_based_clock_mapping` is set to `true`.

timing_context_port_based_clock_mapping

`timing_context_port_based_clock_mapping {true | false}`

Default: `false`

Data_type: Boolean

Enables clock mapping based on block ports.

When set to `true`, clock mapping is done depending solely on clock property of the top and block clock for each clock and data port separately. For enabling N-to-1 or 1-to-N clock mapping, this attribute should be set `true`.

When set to `false`, only 1-to-1 clock mapping is done. In such cases, the following rules are used to determine clock mapping:

- Rule1: Clocks with matching property (period/duty cycle)
- Rule2: Clocks with matching name
- Rule3: Clocks present on maximum number common ports
- Rule4: Any one of the matching clocks

For example,

- Consider the following illustration:

When set to `true`, the following mapping will be seen:

Block Port	Block Clock	Mapped top clock
P1	CLK	CLK, TCLK

When set to `false`, CLK will be mapped to CLK according to Rule 2.

Notes:

- The `context_data` property of block port can be accessed only when this attribute is set `true`.
- When set to `true`, the software may increase the pessimism as the worst latency/arrival will be picked for block context analysis.
- If there are multiple block clocks that can be mapped to same top clock on the same block port, then Tempus does not perform auto mapping (when set to `true`). Whereas for the `false` setting, clock mapping is done depending on the above mentioned rules.

timing_consider_late_arrival_for_ssi_derate

```
timing_consider_late_arrival_for_ssi_derate {true | false}
```

Default: false

Data_type: Boolean

Controls constant propagation across sequential cells.

When set to `true`, the software will use the late arrival time for window overlapping evaluation during simultaneous switching input (SSI) analysis.

timing_constraint_disable_min_max_input_delay_worst_casing

```
timing_constraint_disable_min_max_input_delay_worst_casing {true | false}
```

Default: false

Data_type: Boolean

Disables the override of the maximum value (set using the `set_input_delay -max` parameter) from the specified `-min` value.

timing_constraint_enable_detailed_report_invalid_begin_end_points

```
timing_constraint_enable_detailed_report_invalid_begin_end_points {true | false}
```

Default: false

Data_type: Boolean

Enables detailed reporting of invalid begin/end points specified with

the `set_false_path/set_multicycle_path` constraints.

When set to `false`, the software checks only the structural end points.

timing_constraint_enable_report_invalid_begin_end_points

```
timing_constraint_enable_report_invalid_begin_end_points {true | false}
```

Default: `false`

Data_type: Boolean

Enables reporting of invalid begin points/end points specified with the `set_false_path` or `set_multicycle_path` constraint.

timing_constraint_enable_search_path

```
timing_constraint_enable_search_path {true | false}
```

Default: `false`

Data_type: Boolean

Enables search of constraint files from the search path.

timing_constraint_enable_separate_multicycle_data_checks

```
timing_constraint_enable_separate_multicycle_data_checks {true | false}
```

Default: `false`

Data_type: Boolean

Controls multicycle path constraint application on data checks.

timing_constraint_enable_logging

```
timing_constraint_enable_logging {true | false}
```

Default: `false`

Data_type: Boolean

Enables dumping of constraint commands in the log file.

Note: The impact of this attribute is visible only when the constraints are loaded using the `read_sdc` command or the view definition file.

timing_constraint_load_minimal_set_for_automated_eco

```
timing_constraint_load_minimal_set_for_automated_eco {true | false}
```

Default: false

Data_type: Boolean

Skips loading the SDC constraints that are not required in the Tempus session, when the `opt_signoff` command is used. The timing data is obtained from the ECO timing database - this attribute reduces the TAT for designs with complex constraint mode files.

timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency

```
timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency {true | false}
```

Default: false

Data_type: Boolean

Excludes check arc delays from slack computation.

When set to `true`, the software excludes check arc delays from slack computation for paths constrained by the `set_max_delay/set_min_delay -ignore_clock_latency` command.

timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency

```
timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency {true | false}
```

Default: false

Data_type: Boolean

Excludes the input/output delays from slack computation.

When set to `true`, the software excludes the input/output delays from slack computation for paths constrained by the `set_max_delay/set_min_delay -ignore_clock_latency` command.

timing_constraint_path_delay_exclude_unconstrained_endpoints

```
timing_constraint_path_delay_exclude_unconstrained_endpoints {true | false}
```

Default: `false`

Data_type: Boolean

When path delay exceptions are asserted (using the `set_min_delay` or `set_max_delay` commands) with a complete `-from` and `-to` specification, the exception can be applied between any two data path pins. If the constraint assertion includes only a `-from` and/or `-through` argument, then a set of valid endpoints must be established to define the constrained paths. This attribute allows you to configure the set of valid endpoints (inferred `-to` pins) that are selected.

When set to `false`, the set of allowed endpoints is simply all of the endpoints in the combinational fanout of the `-from` and/or `-through` arguments - essentially, wherever the path tracing stops. The path delay constraint will be applied as if there were a `-to` argument specified for each endpoint.

When set to `true`, the software uses different rules to determine the valid set of inferred `-to` endpoints. Only constrained pins in the fanout of `-from` and/or `-through` arguments are considered as valid `-to` endpoints for the constraint. A constrained endpoint will have some type of timing check - such as Setup or Hold already in force on that pin. Additionally, each transition at the endpoints will be examined to determine if each is individually constrained. The path exception will only be applied to the edges that are constrained. As an example, if a register preset or a clear pin was a potential endpoint, then only the edge constrained by the recovery or removal check will have the path delay applied. To apply the path delay constraint to unconstrained endpoints while in this mode, you must specify them explicitly with the `-to`, `-rise_to`, or `-fall_to` parameters of the `set_min_delay` and `set_max_delay` constraints.

timing_constraint_path_delay_include_clock_pin_endpoints

```
timing_constraint_path_delay_include_clock_pin_endpoints {true | false}
```

Default: `false`

Data_type: Boolean

Considers register clock pins as end-points for path delay constraints applied upstream.

When set to `true`, the `set_max_delay` command considers unconstrained paths ending at the register clock pins.

timing_constraint_warn_for_timing_derate_exceeding_max_limit

```
timing_constraint_warn_for_timing_derate_exceeding_max_limit double
```

Default: `100.0`

Value Range: 0 to 100

Data_type: Double

Sets a limit on derate values. If a larger derate value is applied, the derates are still processed. However, the software issues a warning.

Note: It is recommended to specify derate values within the acceptable value range, because large derate values may cause errors during processing.

timing_continue_on_error

```
timing_continue_on_error {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software continues to process if an error occurs when any constraints are used, or during timing analysis, or when a library is read. This attribute does not have any effect on other commands, except constraints or commands related to timing analysis.

When set to `false`, if an error occurs, during timing analysis, library reading, or defined constraints, the software stops processing and exits.

timing_constraint_update_io_latency_averaging_mode

```
timing_constraint_update_io_latency_averaging_mode {rise_fall | rise_only}
```

Default: rise_fall

Data_type: Enum

Controls the analysis to update IO latency for both rise and fall, or for rise only. You can set one of the options - `rise_fall`, `rise_only`.

timing_cppr_opposite_edge_mean_scale_factor

```
timing_cppr_opposite_edge_mean_scale_factor double
```

Default: 1.0

Value Range: 0 to 1

Data_type: Double

Controls the mean delay component for CPPR credit for opposite transition edges at a common pin.

When this attribute is specified, the software provides a finer level configuration of the CPPR credit for reducing Common Path Pessimism Removal (CPPR) in timing analysis. The software allows a certain

amount of CPPR credit in the case of opposite edge transitions to be scaled to a user-specified value, that is between zero credit or full credit provided by the existing controls.

You can use `timing_cppr_opposite_edge_sigma_scale_factor` attribute for adjustment of the sigma component of the CPPR credit. In SOCV analysis mode, you can use both of these attributes to separately control the adjustment of the mean and sigma components of the CPPR credit. In regular static-timing analysis (STA) mode (without SOCV), only the mean scale factor is considered for CPPR adjustment scaling.

timing_cppr_opposite_edge_sigma_scale_factor

`timing_cppr_opposite_edge_sigma_scale_factor double`

Default: 1.0

Value Range: 0 to 1

Data_type: Double

Controls sigma delay component for CPPR credit for opposite transition edges at common pin.

timing_cppr_opposite_edge_sigma_scale_factor_net

`timing_cppr_opposite_edge_sigma_scale_factor_net double`

Default: 1.0

Data_type: Double

Controls the net sigma delay component for CPPR credit for opposite transition edges at the common pin.

The scale factors are applicable only when the common pin has mismatched transitions for the launch and capture paths.

timing_cppr_opposite_edge_sigma_scale_factor_cell

`timing_cppr_opposite_edge_sigma_scale_factor_cell double`

Default: 1.0

Data_type: Double

Controls the cell sigma delay component for CPPR credit for opposite transition edges at the common pin.

The scale factors are applicable only when the common pin has mismatched transitions for the launch and capture paths.

timing_cppr_propagate_thru_latches

```
timing_cppr_propagate_thru_latches {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the CPPR of a timing path crossing a latch (or latches), for example, ff1 -> lat1 -> ff2, is calculated using the common point of the origin device (ff1) and the capture device at the end of the path (ff2).

When set to `false`, the segment-based CPPR calculation is performed, considering the common point of latch (lat1) and the capture device (ff2). This CPPR setting is considered only when the latch thru analysis mode is enabled and a latch thru path exists.

timing_cppr_remove_clock_to_data_pessimism

```
timing_cppr_remove_clock_to_data_pessimism {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, removes clock re-convergence pessimism (CRP) for clock source paths.

timing_cppr_self_loop_mode

```
timing_cppr_self_loop_mode {true | false}
```

Default: true

Data_type: Boolean

When set to `true` in case of self-loop paths, computes CPPR adjustment by taking the difference between early and late clock arrival time of the common point; the clock pin of the flop. A self-loop path is a path that goes from a clock pin of a flop and ends at the data pin of the same flop. However detecting self-loop paths requires runtime, and is design dependant.

When set to `false`, does not detect self-loop paths. In this case, the software computes CPPR adjustment by using the common point as the output pin driving the clock pin of the flop. This might result in better runtime, but less accurate results. The loss of accuracy is the difference between early and late delay of the interconnect portion driving the clock pin.

timing_cppr_skip_clock_reconvergence

timing_cppr_skip_clock_reconvergence {true | false}

Default: false

Data_type: Boolean

Specifies the branch point to use for computing clock path pessimism removal (CPPR) adjustment when there is reconvergence in the clock tree.

When set to `false`, the software uses the branch point closest to the register clock pins where the clocks reconverge. When set to `true`, the software uses the farthest branch point from the register clock pins (that is, the branch point closest to the clock root pin where the clocks diverge).

timing_cppr_skip_clock_reconvergence_for_unmatched_clocks

timing_cppr_skip_clock_reconvergence_for_unmatched_clocks {true | false}

Default: false

Data_type: Boolean

Allows the software to skip re-convergence of unmatched clocks.

When set to `true`, the software uses the farthest branch point from the register clock pins when the launching and capturing clocks are different - the re-converge points are ignored and not searched.

timing_cppr_threshold_ps

timing_cppr_threshold_ps *double*

Default: 20.0 ps

Data_type: Double

Specifies the maximum amount of pessimism that clock path pessimism removal (CPPR) analysis is allowed to leave in the path. The unit is pico seconds. Setting this attribute to a specified value means that all the paths might be reported without having their pessimism removed. This attribute can be used to speed up CPPR analysis run time. The larger the value of the attribute, the faster the run time.

timing_cppr_transition_sense

```
timing_cpvr_transition_sense {normal | same_transition | same_transition_expanded}
```

Default: normal

Data_type: Enum

Specifies the transition sense of the launching and capturing clocks at the common node, to calculate clock path pessimism removal (CPVR).

- **normal:** The CPVR analysis computes the CPVR value even if the launching and capturing clock transitions at the common node are in opposite directions. If the transition sense at the common node are in opposite directions, the pessimism is the minimum of the difference between late and early arrival times for rise and fall clock transitions.
- **same_transition:** The CPVR analysis computes the CPVR value only if the launching clock transition is same as the capturing clock transition at the common node. If the transitions are different, the CPVR value is zero.
- **same_transition_expanded:** The CPVR analysis computes the CPVR value only if the launching clock transition is the same as the capturing clock transition at the common node. If the transitions are different, the software searches until it finds a common point where the transitions are the same, and calculates the CPVR value from that point.

timing_create_clock_default_propagated

```
timing_create_clock_default_propagated {true | false}
```

Default: false

Data_type: Boolean

Enables clocks to be created in propagated mode.

By default, all clocks, created using `create_clock` and `create_generated_clock` commands, are in ideal mode.

When the attribute is set to `true`, all subsequently created regular clocks, derived clocks, and library generated clocks are in propagated mode.

There is no effect on the functionality of `set_propagated_clock` and `set_clock_latency` commands.

timing_default_opcond_per_lib

```
timing_default_opcond_per_lib {true | false}
```

Default: true

Data_type: Boolean

Determines the default operating condition behavior when there is no explicit user operating condition.

When set to `true`, each timing library uses its own internally-defined default operating condition specification.

When set to `false`, the default operating condition of the master library (that is, the first library in the library search list) is used to set the PVT operation point for the entire design. All timing libraries are accessed and derated to that operating point.

timing_defer_mmmc_obj_updates

```
timing_defer_mmmc_obj_updates {true | false}
```

Default: `false`

Data_type: Boolean

By default, the multi-mode multi-corner (MMMC) update commands, `update_constraint_mode` and `update_analysis_view`, actively load new data upon execution. Since all the timing information is reloaded with each update command, executing a sequence of updates can result in multiple reloads and a subsequent degradation of performance and turn-around-time.

When set to `true`, the software allows a sequence of MMMC updates to be accumulated before new data is loaded and analyzed.

If the `set_analysis_view -update_timing` parameter is specified, the software indicates that the MMMC object updates are complete and new configuration can be loaded and analyzed.

For example:

```
update_constraint_mode -name ioTiming -sdc_files {postCtsIO.sdc}
update_constraint_mode -name coreTiming -sdc_files {postCtsCore.sdc}
set_analysis_view -update_timing
```

timing_derate_aocv_dynamic_delays

```
timing_derate_aocv_dynamic_delays {true | false}
```

Default: `true`

Data_type: Boolean

Controls AOCV derating of SI-induced delays.

When set to `false`, AOCV derates will not be applied on dynamic, SI-induced delays, that is, a value of `false` ensures AOCV derating is only applied to the static component of the delay.

When set to `true`, AOCV derating is applied to both static and dynamic arc delay components.

timing_derate_aocv_reference_point

```
timing_derate_aocv_reference_point {true | false}
```

Default: 1

Data_type: Integer

Allows specification of reference point for AOCV factors. As per the current AOCV library definitions, the AOCV reference point is always expected to be set at 1.0.

timing_derate_dynamic_compatibility

```
timing_derate_dynamic_compatibility {true | false}
```

Default: true

Data_type: Boolean

Controls how the `set_timing_derate` command factors that are not specified, using either `-static` or `-dynamic` options, are applied to the delay.

When this attribute is set to 1, the behavior will be compatible with previous releases. In this mode, the static and dynamic components will be summed up before applying derating.

When set to 0, the static and dynamic components will be derated separately and then combined. A setting of 0 is equivalent to using separate derate assertions with the `set_timing_derate -dynamic` and `-static` options explicitly specified.

timing_derate_incremental_adjust_additive_mode

```
timing_derate_incremental_adjust_additive_mode {true | false}
```

Default: false

Data_type: Boolean

Allows the software to accumulate incremental derate values instead of overwriting them.

When set to `false`, the successive application of incremental derating will overwrite any existing

derate value with the new value.

When set to `true`, the successive applications of the incremental derates will be accumulated into a final derate value.

timing_derate_enable_incremental_multiplication_mode

```
timing_derate_enable_incremental_multiplication_mode {true | false}
```

Default: `false`

Controls the overwrite or accumulative mode settings when the `set_timing_derate -multiply` parameter is specified.

When set to `false`, the latest `set_timing_derate -multiply` command will overwrite the previous constraints at the same level.

When set to `true`, all the values in history will be accumulatively multiplied, when multiple `set_timing_derate -multiply` settings are made on the same object.

timing_derate_incremental_multiply_accumulative_mode

```
timing_derate_incremental_multiply_accumulative_mode {true | false}
```

Default: `false`

Data_type: Boolean

Controls the overwrite or accumulative mode settings when the `set_timing_derate -multiply` parameter is specified. You can use this attribute when `timing_derate_enable_incremental_multiplication_mode` is set to `true` (that is, the `-multiply` setting must be enabled).

When set to `false`, the last specified `set_timing_derate -multiply` command will overwrite the previous constraints at the same level.

When set to `true`, all the values saved in history will be accumulatively multiplied, when multiple `-multiply` settings are made on the same object.

Examples

- The following example shows that in overwrite mode, the multiplicative adjustment will be updated to 0.5:

```
set_global timing_derate_enable_incremental_multiplication_mode true
set_global timing_derate_incremental_multiply_accumulative_mode false
set_timing_derate -multiply 1.2
set_timing_derate -multiply 0.5
```

- The following example shows that in accumulative mode, the multiplicative adjustment will be updated to $1.2 \times 0.5 = 0.6$:

```
set_global timing_derate_enable_incremental_multiplication_mode true
set_global timing_derate_incremental_multiply_accumulative_mode true
set_timing_derate -multiply 1.2
set_timing_derate -multiply 0.5
```

timing_derate_ocv_reference_point

```
timing_derate_ocv_reference_point {true | false}
```

Default: 1

Data_type: Integer

Allows specification of reference point for OCV factors. As per the current OCV library definitions, the OCV reference point is always expected to be set at 1.0.

timing_derate_negative_delay_backward_compatibility

```
timing_derate_negative_delay_backward_compatibility {true | false}
```

Default: true

Data_type: Boolean

Controls the effective derate calculation for negative delays. When effective derate is requested for negative delays, the value will be converted according to the negative delay scaling rule, e.g., 2 - positiveVal.

timing_derate_spatial_distance_unit

```
timing_derate_spatial_distance_unit {default | 1um | 1nm}
```

Default: default

Data_type: Enum

Specifies distance units in the SOCV and AOCV library formats.

This attribute supports 3 distance units - default, 1um, and 1nm. The default value is the default units that are derived from the current system units for distance ($\mu\text{m}/\text{nm}$ overrides the default).

Note: The `timing_derate_spatial_distance_unit` attribute should be set before a design is loaded.

timing_derate_voltage_scaling_mode

```
timing_derate_voltage_scaling_mode first_library | snap_to_nearest | interpolate
```

Default: first_library

Data_type: Enum

Controls how timing derates are computed when the analysis voltage is not at the characterization voltage of any of the currently loaded timing libraries. When the timing analysis environment is configured for interpolation, the MMMC library set will contain a list of timing libraries at different voltage characterizations points.

You can specify the following options:

first_library	Derates associated with the first library in the timing library list will be used.
snap_to_nearest	Allows the software to choose one set of derates from the library closest to the required analysis voltage.
interpolate	Allows the timer to perform interpolation of the derates associated with the two bounding reference libraries.

Consider the following example:

```
create_library_set -name ls_interp_1.50V_1.80V  
-timing [list stdcell_1.50V.lib stdcell_1.75V.lib stdcell_1.80V.lib]
```

In this example, by default (`first_library`) the derates associated with the library `stdcell_1.50V.lib` will be used.

When set to `snap_to_nearest`, if the analysis voltage is 1.70V, the derates from the library `stdcell_1p75V.lib` will be used.

When set to `interpolate`, if the analysis voltage is 1.60V, then interpolation of derates from the libraries `stdcell_1.50V.lib` and `stdcell_1.75V.lib` will be used.

If interpolation mode is selected and the analysis voltage is beyond either the smallest or largest voltage, then the library derates will not be interpolated. The derates associated with the nearest bounding library will be used. If the analysis voltage is 1.90V, then only the derates from `stdcell_1.80V.lib` will be used.

If interpolation mode is enabled, but not all the bounding libraries have derate values, a default derate value of 1.0 will be assumed for the missing derates and used for interpolation. A TA-960 warning message will also be issued.

timing_disable_bus_contention_check

```
timing_disable_bus_contention_check {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, disables propagation of maximum delay along three state disable timing arcs and minimum delay along three state enable arcs. If you know that bus contention conditions do not occur in your design, disable these checks by setting these attributes to `true`.

Checks for setup and hold violations in three-state bus designs. Checks the worst delay path to ensure that the latched signals are stable and not unknown values - X. Ensures proper timing checks for bus contention.

timing_disable_clock_period_checks

```
timing_disable_clock_period_checks {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, disables timing model clock period checks during timing analysis.

timing_disable_constant_propagation_for_sequential_cells

```
timing_disable_constant_propagation_for_sequential_cells {true | false}
```

Default: false

Data_type: Boolean

Controls constant propagation across sequential cells.

When set to `true`, the software disables constant propagation across sequential cells.

When set to `false`, the software enables constant propagation across sequential cells.

timing_disable_drv_report_on_constant_nets

```
timing_disable_drv_report_on_constant_nets {true | false}
```

Default: false

Data_type: Boolean

Disables DRV checks for nets that are disabled by constant propagation:

When the attribute is set to `true`, the `report_constraint` command does not report DRV violations for constant nets.

timing_disable_floating_bus_check

```
timing_disable_floating_bus_check {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, disables propagation of minimum delay through three state disable timing arcs and maximum delay through three state enable arcs. These checks are only valid during floating bus conditions.

timing_disable_get_clocks_for_current_instance

```
timing_disable_get_clocks_for_current_instance {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software disables the `current_instance` command support on `get_clocks`.

timing_disable_genclk_combinational_blocking

```
timing_disable_genclk_combinational_blocking  
{true | false}
```

Default: false

Data_type: Boolean

Disables blocking of the latency path for a generated clock.

When set to `true`, allows the latency path to traverse through the upstream generated clock.

When set to `false`, if two back-to-back generated clocks are on the same path, and if the downstream generated clock is set using the `create_generated_clock -combinational` parameter, then the latency path for this generated clock is blocked by the upstream clock. The downstream generated clock is created with zero latency.

timing_disable_inferred_clock_gating_checks

```
timing_disable_inferred_clock_gating_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, disables clock gating checks that are inferred on combinational elements in the clock path. Explicit clock gating checks that are described in the timing library are not affected by this attribute.

timing_disable_inout_output_side_timing_checks

```
timing_disable_inout_output_side_timing_checks {true | false}
```

Default: false

Data_type: Boolean

Disables timing checks on both the input and output sides of the bidirectional pin.

When set to `false`, the timing checks on both the input and output sides of the bidirectional pin are analyzed.

timing_disable_internal_inout_cell_paths

```
timing_disable_internal_inout_cell_paths {true | false}
```

Default: true

Data_type: Boolean

When set to `false`, enables internal bidirectional feedback paths that are completely contained in one instance.

timing_disable_internal_inout_net_arcs

```
timing_disable_internal_inout_net_arcs {true | false}
```

Default: true

Data_type: Boolean

When set to `true`, this attribute disables internal bidirectional feedback paths that span multiple instances.

When set to `false`, this attribute enables internal bidirectional feedback paths, which are feedback paths that you might not want to use during analysis and optimization.

This attribute applies only to paths that span multiple instances. The attribute has no impact on internal feedback paths that are completely contained in one instance.

timing_disable_lib_pulse_width_checks

```
timing_disable_lib_pulse_width_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, disables timing model pulse width checks during timing analysis.

timing_disable_library_data_to_data_checks

```
timing_disable_library_data_to_data_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software disables the timing arcs between any data-to-clock or clock-to-clock checks - when `timing_type` attribute is set to one of the following:

- `non_seq_setup_rising`
- `non_seq_setup_falling`
- `non_seq_hold_rising`
- `non_seq_hold_falling`

This attribute affects non-sequential checks only, where a reference pin of the timing check is a clock pin. The data-to-data checks (where the reference pin of the timing check is a data pin) are not affected by this setting. To disable data-to-data checks you can use the

`timing_disable_library_data_to_data_checks` attribute.

timing_disable_library_tieoffs

```
timing_disable_library_tieoffs {true | false}
```

Default: `false`

Data_type: Boolean

Disables constant functions in a library.

When set to `false`, the software considers constant propagation from library tie high/low cells prior to those from logical netlist and constraints. There may be cases where programmable tie cells are used whose value can be changed later in the flow, assuming the programmable tie cells are modelled with constant output functions.

When set to `true`, the library constants are not propagated during timing analysis or timing optimization.

timing_disable_netlist_constants

```
timing_disable_netlist_constants {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, ignores constants defined in the Verilog netlist. This includes all uses of the in-place constant notation, such as `1'b0`, and the use of power and ground nets. Constants from `set_case_analysis` assertions and from tie-hi and tie-lo cells are still recognized.

When set to `false`, the software recognizes all constants.

timing_disable_model_parasitics

```
timing_disable_model_parasitics {true | false}
```

Default: 0

Data_type: int

Disables saving parasitics data into a model.

When set to `true`, the software will not save parasitics data into the boundary model, so the generated boundary models will occupy a smaller disk space. However, while reading this boundary model at the top level, the original block parasitics (which was used while generating the model) should be read along with the top level parasitics.

When set to `false`, the parasitic data is not stored in the boundary models. Hence, the user does not need to read the block parasitics, since it is read from the boundary models. By default, this attribute is set to `false`.

timing_disable_nochange_checks

```
timing_disable_nochange_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, disables no change timing model checks during timing analysis.

timing_disable_non_sequential_checks

```
timing_disable_non_sequential_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software disables the timing arcs between any data-to-clock or clock-to-clock checks.

This attribute affects non-sequential checks only, where a reference pin of the timing check is a clock pin. The data-to-data checks (where the reference pin of the timing check is a data pin) are not affected by this setting. To disable data-to-data checks you can use the

`timing_disable_library_data_to_data_checks` attribute.

timing_disable_output_as_clock_port

```
timing_disable_output_as_clock_port{true | false}
```

Default: false

Data_type: Boolean

Allows a clock path to be considered as a data path.

When set to `true`, the software allows a clock source path, leading to an output or bidi port, to be treated as a data path, irrespective of constraints, such as, `set_output_delay`, `set_data_check`, or `set_max_delay`, asserted on that port.

When set to `false`, all the clock source paths, leading to output ports, are considered as valid clock end points. Any unconstrained output port may not be considered as data end point.

timing_disable_parallel_arcs

```
timing_disable_parallel_arcs {true | false}
```

Default: true

Data_type: Boolean

Enables the software to automatically perform reduction of parallel delay arcs and check arcs to improve efficiency.

When set to `false`, parallel delay and check arc reduction will be disabled.

timing_disable_pulse_width_same_edge_si_cprr_mode

```
timing_disable_pulse_width_same_edge_si_cprr_mode {true | false}
```

Default: true

Data_type: Boolean

Enables SI CPPR credit up to the last divergent pin for pulse width checks for zero width pulse clocks. By default, the software credits minimum of rise and fall transition CPPR up to the common pin as the transitions mismatch at the common pin.

When set to `true`, the software computes base delay CPPR up to the common pin as CPPR credit for the path. The software then finds an alternate common timing pin in the clock network where the transition for launch and capture match. If a match is found, the software includes the SI delay up to this pin in the CPPR credit as well.

timing_disable_report_header_info

```
timing_disable_report_header_info {true | false}
```

Default: `false`

Data_type: Boolean

Controls whether timing reports are generated using a common report header.

When set to `false`, the software generates timing reports with a report header that includes the following information:

- Tempus software version number
- Platform on which the software is being run
- Time when the report was generated
- Command used to generate the report

Any report-specific banner information is included in the same header box, but listed after the common header information.

When set to `true`, the software generates backward-compatible timing reports without the additional header information.

timing_disable_retime_clock_path_slew_propagation

```
timing_disable_retime_clock_path_slew_propagation {true | false}
```

Default: `true`

Data_type: Boolean

When set to `true`, path based analysis is performed on data paths only and the clock segments are not considered.

When set to `false`, analysis is performed on both data and clock paths.

timing_disable_sdf_retain_arc_merging

```
timing_disable_sdf_retain_arc_merging {true | false}
```

Default: false

Data_type: Boolean

Controls handling of retain arcs in SDF2.1.

When set to `false`, the Retain information is merged into SDF 2.1, as Retain represents a valid minimum path timing for a cell.

When set to `true`, the Retain arc merging will be disabled.

timing_disable_skew_checks

```
timing_disable_skew_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, disables library skew checks for timing analysis.

timing_disable_test_signal_arc

```
timing_disable_test_signal_arc {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, timing analysis will not analyze the signal arcs coming from or going to the test pin. Such pins are marked in the timing library with either the `test_scan_in`, the `test_scan_enable` attribute for the input pin, the `test_scan_clock` attribute for the input clock pin, or the `test_output_only` attribute for the output pin.

The following are the equivalent Liberty and TLF pin attributes:

Liberty and TLF Pin Attributes

Type	Liberty	TLF
enable	test_scan_enable	SCAN_PINTYPE (ENABLE)

input	test_scan_in	SCAN_PINTYPE (INPUT)
input clock	test_scan_clock	SCAN_PINTYPE (CLOCK)
output	test_output_only	SCAN_PINTYPE (OUTPUT)

timing_max_transition_use_si_transition

```
timing_max_transition_use_si_transition {true | false}
```

Default: false

Data_type: Boolean

Enables reporting of noisy slew in DRV flows.

timing_model_netlist_exclude_dummy

```
timing_model_netlist_exclude_dummy {true | false}
```

Default: false

Data_type: Boolean

Excludes the dummy cell definitions that are written to the model netlist.

timing_disable_timing_model_latch_inferencing

```
timing_disable_timing_model_latch_inferencing {true | false}
```

Default: true

Data_type: Boolean

Controls whether latch behavior is inferred for cell descriptions tagged with the Liberty `timing_model_type` attribute, including all values: `abstracted`, `extracted`, or `qtm`.

When set to `false`, the software infers latch behavior from the timing check and timing delay arc relationships in the model's description.

When set to `true`, latch inferencing does not happen for cells with the `timing_model_type` attribute. Explicit Liberty latch modelling constructs must be coded into the description in order to model latch behavior.

This attribute does not affect Liberty timing model cells that do not contain the `timing_model_type` attribute. Standard cell core libraries generally do not have this attribute specified; therefore, they typically are not be affected by this attribute setting.

timing_disable_tristate_disable_arcs

```
timing_disable_tristate_disable_arcs {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, disables all 0/1->Z transitions of tristate arcs during timing analysis. By default, all tristate arcs are enabled.

timing_disable_user_data_to_data_checks

```
timing_disable_user_data_to_data_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, disables data to data checks that are created by the `set_data_check` command. This attribute does not affect non-sequential timing checks described in the timing library.

timing_driving_cell_override_library

```
timing_driving_cell_override_library {true | false}
```

Default: false

Data_type: Boolean

Controls the selection of library cells specified using the `set_driving_cell` command.

When set to `true`, a driving cell will be picked up from the Max Library for max drive cell adjustment and Min Library for min drive cell adjustment, irrespective of the library specified with the `set_driving_cell - library` parameter.

When set to `false`, the libraries are selected as specified with the `set_driving_cell` command.

timing_drv_analysis_ignore_latency_phases

```
timing_drv_analysis_ignore_latency_phases {true | false}
```

Default: false

Data_type: Boolean

Enables ignoring latency phases in DRV analysis.

timing_enable_aocv_slack_based

```
timing_enable_aocv_slack_based {0 | 1}
```

Default: false

Data_type: Boolean

Enables AOCV analysis using slack-based method.

When set to `true`, the software will try to remove excess pessimism from the graph-based analysis (GBA) AOCV stage counts. The paths to endpoints, which are under the specified slack criteria (default 0.0 ns), are considered when computing stage counts. This allows the stage counts and subsequent AOCV derates to be aligned with the failing paths – and not unnecessarily punished by derates coming from related short paths that meet timing requirements.

Note: This setting is not recommended for signoff timing analysis in Tempus. For signoff, path-based analysis (PBA) is the recommended flow for removing excess GBA pessimism.

timing_enable_case_analysis_conflict_warning

```
timing_enable_case_analysis_conflict_warning {true | false}
```

Default: true

Data_type: Boolean

Displays a warning when propagated and asserted constant values are not the same when a full timing update is performed.

When set to `true`, a report file, named `CTE_constant_mismatch.rpt`, is generated that contains details of pins and the reason for constant mismatch. This report is over-written each time a full timing update takes place.

timing_enable_clock_to_clock_clock_gating_check

```
timing_enable_clock_to_clock_clock_gating_check {true | false}
```

Default: false

Data_type: Boolean

Enables clock-to-clock clock gating checks.

When set to `true`, the software performs clock to clock gating checks at gating elements. For clock to clock gating checks, the frequency of a clock arriving at the reference side of a check should be equal to or greater than the frequency of the clock arriving at the signal side of the check.

timing_enable_clock_phase_based_rise_fall_derating

```
timing_enable_clock_phase_based_rise_fall_derating {true | false}
```

Default: false

Data_type: Boolean

Determines the interpretation of edge-specific derating factors for clock paths, specified using the `set_timing_derate -rise/-fall` parameters.

When set to `false`, the `set_timing_derate -rise/-fall` parameter refer to the direction of the transition from the perspective of each individual output pin along the clock path.

When set to `true`, the `-rise/-fall` parameter refers to which edge (or phase) of the clock is triggering the transition as viewed from the source of the clock where the clock waveform is defined.

timing_enable_data_through_clock_gating

```
timing_enable_data_through_clock_gating {true | false}
```

Default: true

Data_type: Boolean

When set to `false`, blocks signals arriving on the enable of the clock-gating check.

When set to `true`, allows both data and clock signals at the enable pin of a clock-gating check to propagate forward past the check.

timing_enable_db_attribute_query

`timing_enable_db_attribute_query {true | false}`

Default: `true`

Data_type: Boolean

Allows to query DB attributes with the `get_property` command.

timing_enable_derating_for_pulse_width_checks

`timing_enable_derating_for_pulse_width_checks {true | false}`

Default: `false`

Data_type: Boolean

Controls whether the cell check derates, set by `set_timing_derate -cell_check` command, can be applied for pulse width checks.

When set to `true`, the pulse width checks honor cell check derate factors.

timing_enable_early_late_data_slews_for_setuphold_mode_checks

`timing_enable_early_late_data_slews_for_setuphold_mode_checks {true | false}`

Default: `false`

Data_type: Boolean

Controls calculated delays.

When set to `true`, the software allows use of both the minimum and maximum data slews for setup and hold checks. By default, the minimum or maximum slew values for clock pins are considered, and for data pins only the maximum slew value is considered while calculating the setup/hold timing check values.

The `timing_enable_early_late_data_slews_for_setuphold_mode_checks` attribute enables an eight-way timing check for:

- Early/late libraries
- Clock/data pins

- Min/max slews

You can use this attribute in simultaneous setup or hold mode only. To enable this mode, you need to set `timing_enable_simultaneous_setup_hold_mode` attribute to `true`. In this mode, you can use the `report_delay_calculation` command (`-from` and `-to` parameters) to report all the setup/hold check values corresponding to minimum/maximum combination of clock and data slews.

timing_enable_genclk_divide_by_inherit_parent_duty_cycle

```
timing_enable_genclk_divide_by_inherit_parent_duty_cycle{true | false}
```

Default: `false`

Data_type: Boolean

Controls inheritance of duty cycle from master clock for generated clocks with divide by option.

timing_enable_genclk_source_path_register_limit

```
timing_enable_genclk_source_path_register_limit {true | false}
```

Default: `false`

Data_type: Boolean

Limits generated clock source latency path to traverse across one register only.

When set to `false`, the software allows master clock latency path to traverse across any number of sequential devices to reach the generated clock target pin.

When set to `true`, the software restricts the master clock latency path for a generated clock to traverse exactly one sequential device.

timing_enable_generated_clock_edge_based_source_latency

```
timing_enable_generated_clock_edge_based_source_latency {true | false}
```

Default: `true`

Data_type: Boolean

Controls how the software chooses generated clock source latency paths. Certain specifications of the `create_generated_clock` constraint imply a cause-and-effect relationship between the edges of the master clock and those of the generated clock.

When set to `true`, the software checks whether a path being analyzed has the correct cause-effect relationship consistent with the specified constraint. Paths that are found to be inconsistent are ignored. Only the paths that are in agreement with the required edge relationship are considered for source latency. If no such path exists, the software uses a source latency of 0 ns. This selection is done independently for each edge of the generated clock; therefore the result might be different for each edge.

The edge-to-edge sufficiency checks are performed assuming a Rise-to-Rise, Rise-to-Fall relationship between the master clock and the generated clock with an even number `-divide_by` factor. For the odd `-divide_by` factors, the sufficiency check is performed assuming a Rise-to-Rise, Fall-to-Fall relationship. The sufficiency checking is not performed for `-multiply_by` options.

When set to `false`, the software does not check paths for the correct cause-effect relationship.

timing_enable_get_obj_escaped_name_backward_compatible

```
timing_enable_get_obj_escaped_name_backward_compatible {true | false}
```

Default: false

Data_type: Boolean

Enables printing of escape characters in the `get_object_name` command output.

timing_enable_get_objects_regexp_compatibility

```
timing_enable_get_objects_regexp_compatibility {true | false}
```

Default: false

Data_type: Boolean

Defines the pattern search scope to boundaries deduced from hierarchy separation characters specified in the search pattern.

When set to `false`, the commands with `-regexp` parameter will search at the top level only (unless used with the `-hier` parameter).

When set to `true`, the commands will search the specified pattern within the hierarchies based upon the given pattern hierarchy (similar to pattern search without the `-regexp` parameter). The `-hier` along with the `-regexp` parameter shows the same behavior similar to when the command is used without the `-regexp` option - only the leaf level object name is compared to the pattern match.

Examples

Command behavior when this attribute is set to `false`:

```
get_pins -regexp seg2/.* /QN
```

```
**WARN: (TCLCMD-513): The software could not find a matching object of the specified type for
```

the pattern '.*/*.*'

```
**ERROR: (TCLCMD-917): Cannot find 'pins' that match 'seg2/.*/QN'
```

```
get_pins -regexp seg2/.*/QN -hier  
seg2/u3/QN seg2/u9/QN seg2/u14/QN
```

```
get_pins -regexp .*/QN -hier  
seg1/u3/QN seg1/u9/QN seg1/u14/QN seg2/u3/QN seg2/u9/QN seg2/u14/QN seg3/u3/QN seg3/u9/QN  
seg3/u14/QN u2/QN u5/QN u8/QN
```

Command behavior when this attribute is set to `true`:

```
get_pins -regexp seg2/.*/QN  
seg2/u3/QN seg2/u9/QN seg2/u14/QN
```

```
get_pins -regexp seg2/.*/QN -hier  
**WARN: (TCLCMD-513): The software could not find a matching object of the specified type for  
the pattern '.*/*.*'  
**ERROR: (TCLCMD-917): Cannot find 'pins' that match 'seg2/.*/QN'
```

```
get_pins -regexp .*/QN -hier  
seg1/u3/QN seg1/u9/QN seg1/u14/QN seg2/u3/QN seg2/u9/QN seg2/u14/QN seg3/u3/QN seg3/u9/QN  
seg3/u14/QN u2/QN u5/QN u8/QN
```

timing_enable_hier_context_unmapped_clock_analysis

```
timing_enable_hier_context_unmapped_clock_analysis {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, for unmapped block clocks, the software enables timing analysis based on the block SDC constraints set on block ports.

timing_enable_hierarchical_get_nets_support

```
timing_enable_hierarchical_get_nets_support {true | false}
```

Default: false

Data_type: Boolean

Enables the hierarchical segment support for nets that are specified using the `get_nets` command.

When set to `false`, the `get_nets` command will report only flat nets.

timing_enable_individual_distance_inter_die_analysis

```
timing_enable_individual_distance_inter_die_analysis {true | false}
```

Default: false

Data_type: Boolean

Enables individual inter-die calculation in 3DIC analysis.

timing_enable_latch_thru_mode

```
timing_enable_latch_thru_mode {true | false}
```

Default: false

Data_type: Boolean

Enables the latch through analysis mode in which timing paths can propagate across latches, depending on their arrival time with respect to the latch transparency window.

When set to `true`, the arrival and required times will be propagated across a latch if it is in transparent mode. The reporting will show the entire flow through the path, rather than individual segments. This allows the overall path slack to be seen through upstream borrowing latch stages. The timing analysis, timing optimization, and reporting will consider the sequence of borrowing latch stages as a single path. As a result, the timing optimization reaches the target slack by viewing the entire path.

This feature provides better visibility into the overall context of latch path timing issues - for both the stage and path-level slacks. Additionally, this improves usability for debugging and manual ECOs, and shows better quality of result for Tempus ECO timing closure.

timing_enable_latency_through_clock_gating

```
timing_enable_latency_through_clock_gating {true | false}
```

Default: true

Data_type: Boolean

Allows propagation of latency phases across clock gating elements.

When set to `true`, the software allows propagation of clock latency phase across clock gating elements.

When set to `false`, the software suppresses propagation of clock latency across clock gating elements from the enable pin. The enable pin of the clock gating element should not be in the clock network for

any other clocks. This is not recommended because the enable path (through the 'inferred' clock gates, such as, AND, NAND, OR) is either for clock latency or data paths. If the gated clock check is met, then the enable should not pass through to the output.

In case of ICGs, there is no arc from the EN to the CLKOUT on ICGs that have an incoming enable signal latched. In case of ICG/AND, using the enable path may not be correct for determining latency paths. If no latency paths are found, then the generated clocks definition will need to be re-checked.

timing_enable_mmmc_loop_breaking

```
timing_enable_mmmc_loop_breaking {true | false}
```

Default: true

Data_type: Boolean

When set to `true`, loop breaking is handled independently per analysis view, according to the following rules in order of precedence:

- If an analysis view does not contain a combinational loop, it does not inherit any loop breaking done for other views.
- If a loop exists, and the user has supplied specific case analysis and `set_disable_timing` constraints to break the loop at a certain place, the specified loop break is honored.
- If a loop is still detected, the software automatically selects a point to break the loop, and applies the loop break consistently to any views where the loop exists.

When set to `false`, if a combinational loop is detected in any analysis view, the timing system breaks the loop by disabling an arc along the looping path. These combinational loop breaks are reflected in all analysis views, even if those views by themselves do not contain these looping paths.

Note: Cadence recommends that all combinational loops detected by the software be evaluated, to ensure that the loop is broken at the most ideal location. Automatic loop breaking decisions are made based on how the design is traversed. Small changes in the design can influence where loop breaking decisions are made.

To reduce risk and the need to re-evaluate loop-breaking decisions, it is highly recommended that once combinational loop breaks have been evaluated, the user add constraints to ensure that the loop is always broken in that location.

timing_enable_model_constraint_warnings

`timing_enable_model_constraint_warnings integer`

Default: 0

Data_type: Integer

Allows the software to report ignored warnings generated from boundary modeled blocks while processing constraints. These warnings can be reviewed later for debugging purposes.

When set to 0, the software suppresses the constraint warnings.

timing_enable_multi_drive_net_reduction_with_assertions

`timing_enable_multi_drive_net_reduction_with_assertions {none | delay | all}`

Default: none

Data_type: Enum

Allows reduction of multi-drive networks when constraint assertions are present on the network elements:

The following options are available:

- **none:** Reduction is not performed on portions of the network where constraints have been asserted.
- **delay:** Reduction of the multi-drive network will still be applied if only `set_annotated_delay` and `set_annotated_transition` constraints have been applied. Other constraints present on the multi-drive network can still prevent full reduction.
- **all:** The software ignores the presence of any assertions on the multi-drive network and forces reduction to occur.

timing_enable_multi_frequency_latch_analysis

`timing_enable_multi_frequency_latch_analysis {true | false}`

Default: false

Data_type: Boolean

Enables multi-frequency latch timing analysis of the latch time borrowing for when a data signal coming to a latch is controlled by a clock with a frequency different to a clock of the latch enabling signal.

timing_enable_multicycle_data_check_compatibility

```
timing_enable_multicycle_data_check_compatibility {true | false}
```

Default: false

Data_type: Boolean

Enables checking for SDC compatible data checks when `set_multicycle_path -start` parameter is specified.

timing_enable_path_delay_to_unconstrained_endpoints_compatibility

```
timing_enable_path_delay_to_unconstrained_endpoints_compatibility {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software does not constrain paths with path delay - if the path ends at an unconnected input pin of a combination cell.

timing_enable_pessimistic_cppr_for_reconvergent_clock_paths

```
timing_enable_pessimistic_cppr_for_reconvergent_clock_paths{true | false}
```

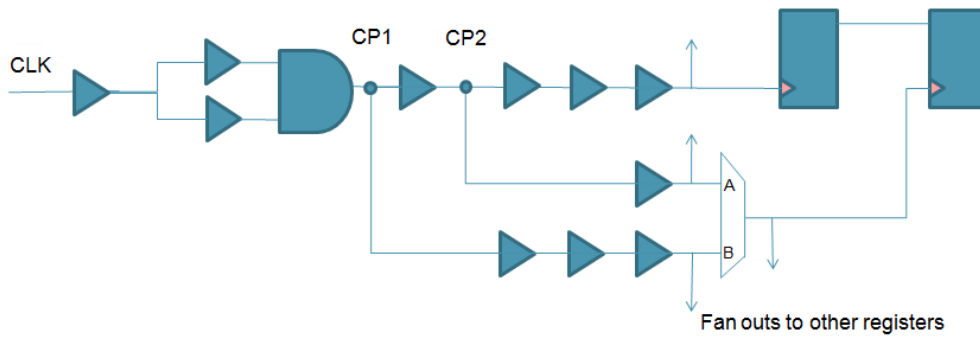

Default: false

Data_type: Boolean

When set to `true`, the software will consider all combinations of launch and capture clock path pairs to identify all possible common pins, and then selects the pin with minimum CPPR adjustment over all such common pins as the common pin.

When set to `false`, the default, the software will choose the CPPR common pin based on the commonality of the worst launch and worst capture path only.

Consider the following example,

In the above diagram, both capture paths are considered along with the single launch path, and the common pin is chosen as the pin with the least CPPR adjustment. The pin CP1 is chosen as a common pin and CPPR is reported up to this pin. The same common pin, CP1, will be used for CPPR adjustment whether the capture clock path goes through the mux A pin or the mux B pin. When this attribute is set to false, CPPR common pin is chosen by the commonality in the worst-case launch and worst-case capture paths. so CP2 is chosen as the common pin and CPPR is reported up to this pin.

timing_enable_power_ground_constants

```
timing_enable_power_ground_constants {true | false}
```

Default: false

Data_type: Boolean

Determines if case analysis is inferred from power and ground rail connections/nets, e.g., VDD and GND.

When set to `true`, the software recognizes the constants that come from power and ground rail connections.

When set to `false`, the software ignores these constants. This provides the most intuitive behavior with logical style netlist (and other tools that do not read physical data).

timing_enable_preset_clear_arcs

```
timing_enable_preset_clear_arcs {true | false}
```

Default: false

Data_type: Boolean

Determines whether the timing arcs are created to model the transition to active state (assertion) of the preset or clear pin, and the subsequent transition of the output to a controlled state.

When set to `true`, the software builds the arcs and the timer automatically analyzes paths through them

(enable clock propagation through preset clear pins).

When set to `false`, the software does not build these arcs, because they are associated with analyzing the reset mode timing paths. Filtering them prevents unwanted interaction with functional mode timing analysis.

Note: The `timing_enable_preset_clear_arcs` attribute can also impact delay calculation results of a design. When an arc is disabled, the software will calculate delay using the linear table lookup. When an arc is not disabled, the delay calculations are made based on the quadratic table lookup.

Note: This attribute should be set to `true` when reset checks are performed on a dedicated reset SDC.

timing_enable_pulse_latch

```
timing_enable_pulse_latch {true | false}
```

Default: `true`

Data_type: Boolean

Enables pulse-latch analysis.

When set to `true`, the pulse-latch analysis mode provides several additional pulse-clock specific constraint specifications and reporting capabilities.

When in pulse-latch mode, you can use the following pulse clock constraints:

- `set_pulse_clock_max_width`
- `set_pulse_clock_min_width`
- `set_pulse_clock_max_transition`
- `set_pulse_clock_min_transition`

Additionally, in this mode the `report_constraint` command supports the following pulse clock check types:

- `pulse_clock_max_width`
- `pulse_clock_min_width`
- `pulse_clock_max_transition`
- `pulse_clock_min_transition`

timing_enable_si_cppr

```
timing_enable_si_cppr {true | false}
```

Default: true

Data_type: Boolean

Enables more accurate CPPR analysis when incremental delays are present.

When set to `true`, the incremental delay is not included in the CPPR calculation during setup analysis, but it is included in the CPPR calculation during hold analysis.

When set to `false`, the incremental delay is included in both setup and hold CPPR calculations.

timing_enable_simultaneous_setup_hold_mode

```
timing_enable_simultaneous_setup_hold_mode {true | false}
```

Default: true

Data_type: Boolean

Controls whether setup and hold checks are analyzed separately, or together on the same timing graph.

When set to `false`, switches the system from analyzing setup slacks to analyzing hold slacks.

When set to `true`, setup and hold slacks are analyzed concurrently. As a consequence, both `-early` and `-late` queries for reporting commands such as `report_timing` can be satisfied immediately, without additional calculation. Simultaneous mode is useful for immediately understanding the consequences to both setup and hold slacks from what-if operations and manual ECOs to the design.

Note: Simultaneous setup and hold mode can be used only for timing analysis; it cannot be used for any physical implementation steps.

Note: This attribute must always be true while running SI analysis.

timing_enable_spatial_derate_mode

```
timing_enable_spatial_derate_mode {true | false}
```

Default: true

Data_type: Boolean

Enables the spatial derate mode in SOCV analysis.

timing_enable_timing_window_pessimism_removal

```
timing_enable_timing_window_pessimism_removal{true | false}
```

Default: false

Data_type: Boolean

Removes pessimism in SI impact calculation. As a result of elongated arrival windows of attackers and victims, there may be pessimism in SI impact calculation due to a difference in the minimum-maximum arrivals of common clock paths shared between attackers and victims. This pessimism can be removed by adjusting attacker/victim arrival window with the difference in minimum-maximum delay of common clock path between victim and attacker.

When set to `true` (when CPPR is enabled), the software adjusts the timing windows of attackers/victims when the victim is located either on a data path or a clock path during path-based analysis.

For adjustment on victim nets lying on clock paths, full path path-based analysis can be enabled by setting the `timing_disable_retime_clock_path_slew_propagation` attribute to `false`.

timing_enable_tristate_clock_gating

```
timing_enable_tristate_clock_gating {true | false}
```

Default: false

Data_type: Boolean

The timing system infers gated-clock checks in the design where a data and clock path intersect at a combinational device. When this attribute is set to `true`, inferred gated-clock checks are added when clock and data signals converge through the tristate enable and data input of tristate buffers. By default (a setting of `false`), gated-clock checks are not added for these situations.

timing_enable_uncertainty_for_clock_checks

```
timing_enable_uncertainty_for_clock_checks {true | all | false | none | pulse_width | period  
| skew}
```

Default: true

Data_type: Boolean

Considers clock uncertainty when performing clock checks.

When set to `true`, the `set_clock_uncertainty` command supports clock uncertainty for period, pulse

width, skew, and separation checks.

Note: This attribute overrides the `timing_enable_uncertainty_for_pulse_width_checks` setting.

timing_enable_uncertainty_for_pulse_width_checks

```
timing_enable_uncertainty_for_pulse_width_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, considers clock uncertainty when performing minimum pulse width checks. Clock uncertainty is considered during checks of both user-defined minimum pulse widths (using the `.lib`).

Note: Specifying a value of `true` affects the following commands that take minimum pulse width checks into account:

- `report_timing -check_type pulse_width`
- `report_timing -check_clocks`
- `report_min_pulse_width`
- `report_analysis_coverage`

timing_enable_vtskew_derate_mode

```
timing_enable_vtskew_derate_mode {true | false}
```

Default: false

Data_type: Boolean

Enables voltage threshold (VT) skew analysis.

When set to `true`, the software analyzes the effects of VT skew in a multi-VT environment.

Due to variations in the manufacturing process, the voltage threshold (Vth) of a given Vth class (e.g., SVT, LVT, ULVT) can show some variations that might result in cells of that class operating either faster or slower than the nominal value. The Vth skew analysis automates the process of selecting which Vth permutations need to be run, which ensures a robust analysis and optimizes the software to run faster and efficiently.

timing_enable_wire_variation

timing_enable_wire_variation {true | false}

Default: false

Data_type: Boolean

Enables wire variation analysis in path-based analysis mode.

timing_enable_zero_delay_analysis_mode

timing_enable_zero_delay_analysis_mode
{true | false}

Default: false

Data_type: Boolean

When set to `true`, the software will use zero delays during timing analysis.

timing_extract_model_aocv_mode

timing_extract_model_aocv_mode {graph_based | path_based | none}

Default: none

Data_type: Enum

Allows you to specify AOCV derating mode.

The valid values are described below:

- `graph_based`: Specifies that the delays in the timing model are derated using the graph-based stage counts.
- `path_based`: Specifies that the delays in the timing model are derated using the total path stage count of worst path between those pin pairs.
- `none`: Specifies that the delays in the timing model are under-rated base delays.

Note: Before setting this attribute to `graph_based` or `path_based` mode, it is mandatory that the AOCV libraries are read in and AOCV analysis is enabled.

timing_extract_model_case_analysis_in_library

```
timing_extract_model_case_analysis_in_library {true | false}
```

Default: true

Data_type: Boolean

Enables the software to model the constants as a function in the extracted timing model.

When set to `true`, the software models constants as functions in the library if these propagate to the output port.

When set to `false`, instead of modeling constants as functions inside the library, these are written as `set_case_analysis` in the constraints file (*.asrt).

timing_extract_model_check_arcs_as_lvf

```
timing_extract_model_check_arcs_as_lvf {true | false}
```

Default: true

Data_type: Boolean

Enables check arcs to be modeled as LVF arcs. By default, the check arcs will be written as nSigma numbers.

The software allows you to write mean+/-nSigma values for constraint arcs, while writing separate mean and sigma values for delay and transition data. This can be enabled by setting `timing_extract_model_check_arc_as_lvf` attribute to `false` and `timing_extract_model_write_lvf` attribute to `true`.

timing_extract_model_consider_design_level_drv

```
timing_extract_model_consider_design_level_drv{true | false}
```

Default: true

Data_type: Boolean

Considers `set_max_capacitance` and `set_max_transition` DRV constraints, that have been applied on the current design during model extraction.

When set to `true`, these constraints applied at the design level will be considered during model extraction. However, the maximum capacitance and maximum transition from various DRV constraints applied/inferred on the ports is considered.

When set to `false`, the software extracts the worse-case DRV values and the constraints applied on the current design will be ignored.

timing_extract_model_disable_cycle_adjustment

```
timing_extract_model_disable_cycle_adjustment {true | false}
```

Default: false

Data_type: Boolean

Controls cycle adjustment for multi-cycle paths.

When set to `false`, if the multi-cycle paths specified in the SDC at the block-level cannot be pushed out to the ports (since there are other paths going through these paths), then the Tempus software adjusts the delay/check numbers in the ETM to take into account the cycle adjustment.

When set to `true`, the cycle adjustment for the multi-cycle paths in ETM arc delay are disabled.

timing_extract_model_enable_combinational_arc_to_clock_source_on_output_ports

```
timing_extract_model_enable_combinational_arc_to_clock_source_on_output_ports {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software models the combinational arc ending on an end point with clock asserted on it.

timing_extract_model_enable_output_pin_attributes

```
timing_extract_model_enable_output_pin_attributes String
```

Default: none

Data_type: String

Specifies the attributes attributes (e.g., `always_on`, `is_isolated`) to enable on output pins during ETM generation. You can use this global variable when backward compatibility with older ETM behavior is required. By default, this global variable is set to `none`.

timing_extract_model_enable_unconstrained_port_modelling

timing_extract_model_enable_unconstrained_port_modelling

{true | false}

Default: false

Data_type: Boolean

Enables extraction of unconstrained paths to the output ports.

When set to `false`, for unconstrained output ports, which have no inbound timing, there will be no arcs modelled for the paths.

When set to `true`, the software will extract dummy arcs inbound to unconstrained output ports that will show the following characteristics:

- Early delay/slew of last stage connected to the output ports will be modelled.
- Related pins will be specified as unique unconstrained internal pins.
- Extracted slew values will be modelled as unidimensional *_transition tables that are dependent on the output capacitance and real propagated slews inside a block.
- Extracted unidimensional delays will be displayed in the cell_* tables.

For more information, refer to "[Timing Model Generation](#)" chapter in the *Tempus Stylus User Guide*.

timing_extract_model_exhaustive_validation_dir

timing_extract_model_exhaustive_validation_dir {true | false}

Default: {}

Data_type: String

Controls the location of files to be stored in the ETM Extremity Validation mode.

When set to `false`, additional files generated during ETM Extremity Validation (but not generated during normal validation) will be stored in the current working directory.

When set to `true`, the location to place these files can be user-specified.

timing_extract_model_exhaustive_validation_mode

```
timing_extract_model_exhaustive_validation_mode{true | false}
```

Default: false

Data_type: Boolean

Enables extracted timing model (ETM) validation at the minimum and maximum indices of the slew load indices.

When set to `false`, the ETM validation is done only for the input slews/output-loads that have been asserted on the design during timing model extraction.

When set to `true`, the software uses the “Extremity-Validation” (EV-ETM) methodology that allows ETM to model the timing arcs in the design for a range of discrete input slews/output-loads, thus providing a more comprehensive validation.

timing_extract_model_gating_as_nochange_arc

```
timing_extract_model_gating_as_nochange_arc {true | false}
```

Default: true

Data_type: Boolean

Controls the conversion of clock gating checks to nochange arcs.

When set to `false`, the software disables conversion of clock gating checks to nochange arcs in the extracted timing model.

timing_extract_model_half_cycle_non_interface_paths

```
timing_extract_model_half_cycle_non_interface_paths {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software models half cycle non-interface paths as MPW (minimum pulse width) checks in ETM.

timing_extract_model_ideal_clock_latency_arc

```
timing_extract_model_ideal_clock_latency_arc{true | false}
```

Default: true

Data_type: Boolean

When set to `true`, the latency arcs for generated clocks that are defined ideal are extracted with reference as master clock, during ETM extraction.

When set to `false`, arcs are not extracted for generated clocks that are defined ideal during ETM extractions.

timing_extract_model_include_applied_load_in_characterization_range

```
timing_extract_model_include_applied_load_in_characterization_range {true | false}
```

Default: `true`

Data_type: Boolean

Specifies that the actual load visible to the timer that will be included in the load characterization range for path end points.

timing_extract_model_include_applied_slew_in_characterization_range

```
timing_extract_model_include_applied_slew_in_characterization_range {true | false}
```

Default: `true`

Data_type: Boolean

Specifies that the actual timer slew must be included in the characterization range timing model.

timing_extract_model_non_borrowing_latch_path_as_setup

```
timing_extract_model_non_borrowing_latch_path_as_setup {true | false}
```

Default: `false`

Data_type: Boolean

Models the non-borrowing interface latch paths as setup checks.

timing_extract_model_slew_propagation_mode

```
timing_extract_model_slew_propagation_mode {worst_slew | path_based_slew}
```

Default: worst_slew

Data_type: Boolean

Specifies the type of slew propagation to use for generating extracted timing model (ETM).

- **worst_slew:** Propagates the worst slew of all the incoming arcs at a converging point for extracting the arcs.
- **path_based_slew:** Propagates the actual slew for the path elements for extracting the arcs.

timing_extract_model_synchronous_clocks_as_skew_checks

```
timing_extract_model_synchronous_clocks_as_skew_checks {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software additionally captures constraints in ETM for reg-to-reg paths, which are launched and captured by different synchronous clocks within the block. The software converts the slack of such paths into a skew-rising/falling constraint requirement between the two clock pins at the IP boundary.

timing_extract_model_write_clock_checks_as_arc

```
timing_extract_model_write_clock_checks_as_arc{true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the clock checks (`min_period` and `min_pulse_width`) are modelled as arcs in the extracted timing models (ETM). Clock check arcs will be modelled as a single dimensional table with constrained and reference pin as clock pin itself.

When set to `false`, clock checks are modeled as scalar numbers in the extracted ETM.

timing_extract_model_write_clock_checks_as_scalar_tables

```
timing_extract_model_write_clock_checks_as_scalar_tables {true | false}
```

Default: false

Data_type: Boolean

Allows the extracted timing model to write the minimum pulse width or minimum period checks as scalar arcs.

timing_extract_model_write_function_for_combinational_arcs

```
timing_extract_model_write_function_for_combinational_arcs {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software writes the function attribute on ports with combinational arcs.

timing_extract_model_write_min_max_clock_tree_path

```
timing_extract_model_write_min_max_clock_tree_path {true | false}
```

Default: true

Data_type: Boolean

Writes the minimum/maximum worst latency for each clock source.

timing_extract_model_write_lvf

```
timing_extract_model_write_lvf {true | false}
```

Default: false

Data_type: Boolean

Generates extracted timing model (ETM) containing Liberty Variation Format (LVF) model.

When set to `true`, this attribute enables writing separate mean and variation tables for all the delay/constraint and transition tables.

When set to `false`, the variation data will be merged with the mean values. The mean +/- nsigma values of delay/constraint/transition data will be written in the ETM.

timing_full_context_flow

`timing_full_context_flow integer`

Default: 0

Data_type: Integer

Enables the full chip timing context mode. This variable captures the estimated slews and timing windows as part of the timing context in the boundary model.

When set to 1, the full chip timing analysis (STA or DSTA) run saves the timing context that is used by the block scope timing later in the flow.

timing_generate_normalized_driver_waveform

`timing_generate_normalized_driver_waveform {0 | 1}`

Default: true

Data_type: Boolean

Generates the analytical normalized driver waveform for timing library if the waveform is not specified in the library. The waveform is generated by weighed mean of linear and exponential waveform.

timing_generated_clocks_inherit_ideal_latency

`timing_generated_clocks_inherit_ideal_latency {false | true | actual_partial_latency_path | ideal_partial_latency_path}`

Default: false

Data_type: Boolean

When the `set_clock_latency` command is used to define network latency for ideal clock mode at intermediate pins of a clock network, Tempus considers the latency. The

`timing_generated_clocks_inherit_ideal_latency` global variable allows including the closest applied network latency for ideal inheritance also. You can use the following options:

- `false`: Uses only the source latency of generated clocks, if it exists.
- `true`: Allows the generated clocks to inherit the ideal network latency of the parent clock.
- `actual_partial_latency_path`: Uses the network latency of the master clock asserted closest to

the target pin and propagated delays for the path from this point to the assertion point of the generated clock.

- `ideal_partial_latency_path`: Uses the network latency of the master clock asserted closest to the target pin and ideal delays for the path from this point to the assertion point of the generated clock.

Note: If the `set_clock_latency -source` parameter is used to specify latency of a generated clock, the software will completely override any inheritance.

timing_generated_clocks_allow_nested_assertions

```
timing_generated_clocks_allow_nested_assertions {true | false}
```

Default: false

Data_type: Boolean

Controls clock latency handling for nested generated clocks that are created on the same timing pin as the master clock.

When set to `true`, the software handles generation of multiple nested generated clocks that are asserted on the same pin, such that the child clock inherits the clock latency value of its parent clock.

When set to `false`, the nested generated clocks asserted on the same pin do not inherit the latency values and are created with 0ns master clock latency. Any full clock timing path reported using these clocks will show the clock path up to the target pin of the generated clock.

timing_get_of_objects_hier_compatibility

```
timing_get_of_objects_hier_compatibility {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the `get_pins -of_objects` parameter will return leaf pins connected to the specified objects.

When set to `false`, the `get_pins -of_objects` parameter will return hierarchical pins and leaf pins connected to the specified objects. In order to return leaf pins only when the attribute is set to `false`, the `-leaf` option must be specified along with the `get_pins -of_objects` parameter.

When set to `true`, the `get_cells -objects` parameter returns cells connected to the net at the same level of hierarchy as the net itself. Hierarchical ports will be returned if the net is connected to a hierarchical module.

timing_hierarchical_context_continue_on_top_block_clock_mismatch

```
timing_hierarchical_context_continue_on_top_block_clock_mismatch {true | false}
```

Default: false

Data_type: Boolean

Allows loading of the timing context model with unmapped clocks.

When set to `true`, the software allows the script to process even if there are any mismatches between the top and block-level clocks. The mismatches are reported in the *timing_context_clock_mapping_data.rpt* file, which shows data that allows you to determine if corrections or additions are required to the clock mapping file.

When set to `false`, the software will show an error if any of the top-level clocks cannot be matched with a block-level clock.

Note: This attribute should not be used for signoff.

timing_hier_obj_name_compatibility

```
timing_hier_obj_name_compatibility {true | false}
```

Default: true

Data_type: Boolean

Controls how hierarchical delimiters are interpreted in the search pattern, when the `-hier` parameter is used with the `get_*collection` commands.

When set to `true`, the software interprets the hierarchical delimiter as part of the search pattern itself, and tries to match names that include the delimiter. For example, if you specify:

```
get_cells -hier L1/R*
```

The software searches at every level of the hierarchy for instances with the name `L1/R*`, completely ignoring the hierarchy separator:

When set to `false`, hierarchical delimiters are interpreted as hierarchy separators. For example, if you specify:

```
get_cells -hier L1/R*
```

The software searched for instances with names matching `R*` in the hierarchy level below `L1`:

```
TL2/L1/RX1 TL2/L1/RX2
```

timing_ignore_clock_based_path_delay_on_data_checks

```
timing_ignore_clock_based_path_delay_on_data_checks {true | false}
```

Default: false

Data_type: Boolean

Disables clock-based path delay application on data checks.

When set to `true`, the Tempus software enables the data checks to be reported by disabling the applied path delay. The "Data Check Setup" details are displayed in the timing report output.

When set to `false`, the timing reports display the "Path Delay" details. By default, this attribute is set to `false`.

timing_ignore_lumped_rc_assertions

```
timing_ignore_lumped_rc_assertions {true | false}
```

Default: false

Data_type: Boolean

When set to `false`, the `set_load` and `set_resistance` values override the actual extracted representation. A warning message is issued stating that the specified constraints on internal nets will override extracted parasitics on those nets.

When set to `true`, instructs the software to ignore `set_load` and `set_resistance` assertions on internal nets in the design. Parasitic data for internal nets normally should be provided by Tempus RC extraction, or external SPEF annotation.

Using `set_load` to specify I/O boundary loading on ports is supported by either setting of this attribute.

timing_io_use_clock_network_latency

```
timing_io_use_clock_network_latency {always | ideal}
```

Default: ideal

Data_type: Enum

Controls whether network latency of a reference clock is added or not to the data arrival time on the port. When set to `ideal`, the `set_input_delay` and the `set_output_delay` constraints will not add the network

latency of the reference clock to the data arrival time on the port if the clock is in `propagated` mode.

When this attribute is set to `always`, network latency is added to the data arrival time on the port regardless of the clock propagation mode.

timing_ipd_allow_paths_for_asynchronous_clocks

```
timing_ipd_allow_paths_for_asynchronous_clocks {true | false}
```

Default: `true`

Data_type: Boolean

When set to `true`, the software will ensure that the paths between the asynchronous clocks are allowed to be treated as IPD (inter-power domain) paths.

For more information, refer to the "Inter Power Domain (IPD) Analysis" chapter in the *Tempus Stylus User Guide*.

timing_ipd_xdomain_path_filtering_threshold

```
timing_ipd_xdomain_path_filtering_threshold double
```

Default: 0.003

Data_type: Double

When this attribute is used, the specified threshold (in ns) will be used in the path filtering criteria during native inter-power domain (xdomain) solution.

timing_library_build_async_deassert_arc

```
timing_library_build_async_deassert_arc {true | false}
```

Default: `true`

Data_type: Boolean

Controls whether input to output arcs from the pre-set or clear pins transitioning to an active state are included, when the timing system is initialized.

timing_library_convert_async_setuphold_to_recrem

```
timing_library_convert_async_setuphold_to_recrem {true | false}
```

Default: 1

Data_type: Integer

Controls whether single-edged setup and hold checks on asynchronous pins in the Liberty library are inferred as recovery and removal checks.

This attribute provides support for older modeling styles in legacy libraries.

timing_library_generated_clock_use_group_name

```
timing_library_generated_clock_use_group_name {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software uses the `generated_clock` group name when creating a generated clock from a library-generated clock group. When set to `false`, the software uses the pin name when creating the generated clock.

For example, assume the cell for instance `a/b` in the timing library contained the following generated clock group:

```
generated_clock(genclk2) {  
  clock_pin : clk1;  
  master_pin : "int/clk";  
  multiplied_by : 2;  
  duty_cycle : 50.0;  
}
```

By default (`false`), the software creates a generated clock with the following name:

```
a/b/clk1
```

If the `timing_prefix_module_name_with_library_generated_clock` attribute is set to `true`, and you set this attribute to `true`, the software creates a generated clock with the following name:

```
a/b/genclk2
```

If the `timing_prefix_module_name_with_library_generated_clock` attribute is set to `false`, and you set this attribute to `true`, the software creates a generated clock with the following name:

```
genclk2
```

timing_library_hold_constraint_corner_sigma_multiplier

`timing_library_hold_constraint_corner_sigma_multiplier double`

Default: 0.0

Data_type: Double

Applies user control multiplier to generate a constraint table using sigma values applied for hold arc.

timing_library_hold_sigma_multiplier

`timing_library_hold_sigma_multiplier double`

Default: 0.0

Data_type: Double

User control multiplier to generate constraint table applied for hold arc.

timing_library_ignore_combinational_arc_mismatch_tables

`timing_library_ignore_combinational_arc_mismatch_tables`

`{true | false}`

Default: false

Data_type: Boolean

When set to `true`, the software will give preference to `timing_type` over arc tables. This will change infer arcs based on the `timing_type` (liberty format) or timing tables settings. A warning message will be displayed when the preference (`timing_type` or arc tables) is changed.

timing_library_infer_async_pins_from_timing_arcs

`timing_library_infer_async_pins_from_timing_arcs {true | false}`

Default: false

Data_type: Boolean

When set to `true`, a pin is marked clear if it has timing arcs with type “clear” to output pins. The

sequential block is not required to be present in the cell for marking a pin as clear.

timing_library_infer_cap_range_from_ccs_receiver_model

```
timing_library_infer_cap_range_from_ccs_receiver_model {true | false}
```

Default: false

Data_type: Boolean

Infers the rise or fall of capacitance range values from CCS receiver capacitance model.

When set to `false`, the rise/fall CCS capacitance range values are not inferred. The NLDM pin capacitance range values defined in the library are honored.

timing_library_infer_cap_range_from_ecsm_receiver_model

```
timing_library_infer_cap_range_from_ecsm_receiver_model {true | false}
```

Default: false

Data_type: Boolean

Infers the rise or fall of NLDM pin capacitance range from the ECSM capacitance range while calculating the total loading capacitance during switching power computation. If the attribute is set to `true` and the capacitance range is not defined in the library, the rise/fall capacitance range is inferred from the ECSM receiver capacitance models. The capacitance range values are derived either from the pin-level ECSM cap models or the timing-level ECSM cap models.

When this attribute is set to `false`, the rise/fall capacitance range values are not inferred, and the library values are honored.

timing_library_interpolate_drv_values

```
timing_library_interpolate_drv_values {true | false}
```

Default: false

Data_type: Boolean

Allows the software to use a range of trilib DRV values for performing delay calculations.

timing_library_infer_socv_from_aocv

```
timing_library_infer_socv_from_aocv {true | false}
```

Default: false

Data_type: Boolean

Controls the transformation of AOCV data.

This attribute infers sensitivity data from AOCV libraries, and must be set before loading any timing library data.

timing_library_read_ccs_noise_data

```
timing_library_read_ccs_noise_data{true | false}
```

Default: true

Data_type: Boolean

This attribute can be used when the CCS library contains noise models, and SI glitch analysis is being performed.

timing_library_read_without_ecsm

```
timing_library_read_without_ecsm {true | false}
```

Default: false

Data_type: Boolean

Disables loading ECSM data.

When set to `true`, the software allows you to change the mode of use (of ECSM timing model) if the timing library contains NLDM, ECSM, or CCS data in the same file.

Note: This attribute does not disable CCS data loading.

timing_library_read_without_power

```
timing_library_read_without_power {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, this attribute allows the software to read timing libraries without power information. When set to `false`, the software reads power data also.

Note: The `get_db` command shows the default value as `false`. However, this global variable is set to `true` by default in Tempus.

timing_library_read_without_sensitivity

```
timing_library_read_without_sensitivity {true | false}
```

Default: `false`

Data_type: Boolean

Disables loading of ECSM timing sensitivity data.

timing_library_scale_aocv_to_socv_to_n_sigma

```
timing_library_scale_aocv_to_socv_to_n_sigma <n_sigma value>
```

Default: `3.0`

Data_type: Double

AOCV derates are expected to be derived based on 3-sigma variation.

timing_library_setup_constraint_corner_sigma_multiplier

```
timing_library_setup_constraint_corner_sigma_multiplier double
```

Default: `0.0`

Data_type: Double

Applies user control multiplier to generate a constraint table using sigma values applied for setup arc.

timing_library_setup_sigma_multiplier

`timing_library_setup_sigma_multiplier double`

Default: 0.0

Data_type: Double

Applies user control multiplier to generate constraint table using sigma values applied for setup arc.

timing_library_term_voltage_from_lib_pin

`timing_library_term_voltage_from_lib_pin int`

Default: 1

Data_type: Integer

Enables the use of library pin voltage for reporting the term voltage.

timing_library_use_two_piece_receiver_cap

`timing_library_use_two_piece_receiver_cap {true | false}`

Default: false

Data_type: Boolean

Enables the use of 2-piece receiver capacitance constructs, if a library contains both the N-piece and 2-piece receiver capacitance construct.

When set to `true`, if a library has 2-piece and multi-piece pin capacitance, then the software gives priority to 2-piece models.

When set to `false`, the software reads the N-piece receiver capacitance constructs.

timing_library_zero_negative_timing_check_arcs

`timing_library_zero_negative_timing_check_arcs {true | false}`

Default: false

Data_type: Boolean

When set to `true`, the software checks for negative values in the timing arcs.

timing_multi_frequency_clock_rounding_factor

timing_multi_frequency_clock_rounding_factor *double*

Default: 1e-05

Data_type: Double

Rounds off irrational numbers so that they can be read appropriately.

timing_normalized_driver_waveform_clip_linear_part

timing_normalized_driver_waveform_clip_linear_part {0 | 1}

Default: false

Data_type: Boolean

When set to 1, the linear ramp component in the normalized driver waveform is saturated to the maximum value, while generating the normalized driver waveform.

timing_normalized_driver_waveform_weight_factor

timing_normalized_driver_waveform_weight_factor *double*

Default: 0.5

Data_type: Double

Defines the value of the weight of linear components in the algorithm for generation of normalized driver waveform.

When set to 1, the waveform will be purely linear. When set to 0, the waveform will be purely exponential. You can specify values within the range of 0 to 1.

timing_nsigma_multiplier

timing_nsigma_multiplier *double*

Default: 3.0

Data_type: Double

Controls the sigma multiplier to be used in SOCV mode.

timing_null_collection_return_compatibility

```
timing_null_collection_return_compatibility {true | false}
```

Default: false

Data_type: Boolean

Allows you to migrate previous release scripts to the new use model.

When the attribute is set to `true`, the software returns "NA" values that are consistent with the previous release. The nil return values are returned as an empty collection. This allows the return value to be used directly by collection iterators, such as `foreach_in_collection`.

The default value is `false`, which is consistent with the current release.

Note: This compatibility option may be removed from future releases. You should update your scripts to the new use model to avoid future problems.

timing_path_based_enable_bounding_box_for_io_paths

```
timing_path_based_enable_bounding_box_for_io_paths {true | false}
```

Default: false

Data_type: Boolean

Enables the bounding box mode for input-output paths.

timing_path_based_enable_closest_common_pin_driver_for_bounding_box

```
timing_path_based_enable_closest_common_pin_driver_for_bounding_box {true | false}
```

Default: false

Data_type: Boolean

Enables bounding box calculation using closest common pin driver from the clock mesh.

timing_path_based_epba_bounded_mode

```
timing_path_based_epba_bounded_mode {true | false}
```

Default: `false`

Data_type: Boolean

Enables the IPBA mode with exhaustive PBA analysis (run using the `report_timing - retime_mode exhaustive` command).

When set to `true`, the software ensures that all the paths to the violating endpoints are covered for PBA, and the slack is the worst PBA slack reported across all the paths to the endpoint. For any endpoint that is considered for IPBA analysis, the complete fanin cone (all the timing paths ending at that endpoint) is evaluated for any possible PBA violation.

timing_path_based_enable_report_launch_clock_path

```
timing_path_based_enable_report_launch_clock_path {true | false}
```

Default: `true`

Data_type: Boolean

When set to `false`, the software skips the reporting launch clock path in PBA path_type full report.

timing_path_based_enable_verbose_mode

```
timing_path_based_enable_verbose_mode value
```

Default: `1`

Data_type: Enum

Controls printing of verbose messages during and at the end of path-based analysis (PBA).

You can specify one of the three values - 0, 1, and 2. These are described below:

- `0`: Verbose messages are not reported during exhaustive PBA analysis. For default PBA analysis, the path count will be reported.
- `1`: Reports the final message for PBA path count and max depth reached during exhaustive PBA. Progress messages are not reported.
- `2`: Reports multiple progress messages after regular intervals (in addition to the final message for PBA path count and max depth).

This attribute impacts messages when the `report_timing` and `report_constraint` commands are used in PBA mode.

For example,

- The following commands print messages during and after PBA analysis:

```
set_db timing_path_based_enable_verbose_mode 2
report_timing -retime path_slew_propagation -retime_mode exhaustive -max_paths 500000 -
nworst 1
```

The following progress messages are displayed during PBA analysis:

```
INFO: Path Based Analysis (PBA) currently performed on '108455' paths
INFO: Path Based Analysis (PBA) currently performed on '217574' paths
INFO: Path Based Analysis (PBA) currently performed on '327511' paths
INFO: Path Based Analysis (PBA) currently performed on '437472' paths
....
```

The following messages are displayed at the end of PBA analysis mentioning the PBA path count and max depth reached during exhaustive PBA:

```
INFO: Path Based Analysis (PBA) performed on total '2660526' paths
INFO: Max depth 9460 reached for end point 'top/hier1/hier2/flop/d' during Path Based
Analysis
```

timing_path_based_enable_exhaustive_depth_bounded_by_gba

```
timing_path_based_enable_exhaustive_depth_bounded_by_gba
{true | false}
```

Default: true

Data_type: Boolean

Enables the timing report to bound PBA results by GBA slacks of the respective leftover nworst paths, whenever exhaustive PBA depth for an endpoint is exhausted.

When set to `true`, during exhaustive PBA, if you specify exhaustive depth as N, and an endpoint has nworst paths greater than N, then the timing report will show the worst path corresponding to worst slack out of worst PBA slack (out of first N paths) and GBA slack (for the (N+1)th path). Here, the variable N refers to exhaustive PBA depth and can be set using the `timing_pba_exhaustive_path_nworst_limit` attribute.

When set to `false`, during exhaustive PBA, if you specify exhaustive depth as N, and an endpoint has nworst paths greater than N, then the software will ignore the paths with depth greater than N, which may result in reporting an optimistic PBA slack for the endpoint reaching the depth.

timing_path_based_exhaustive_enable_design_coverage

timing_path_based_exhaustive_enable_design_coverage
{true | false}

Default: false

Data_type: Boolean

Enables exhaustive path-based analysis (PBA) to automatically pick up and analyze all the violating endpoints in the design, irrespective of the specified maximum paths.

When set to `true`, exhaustive PBA analysis automatically picks up and analyzes the violating design endpoints instead of N endpoints (specified with the `report_timing -max_paths` parameter). After analyzing the violating endpoints, the software reports the top N worst endpoints - depending on the specified value of N.

When set to `false`, exhaustive PBA analysis restricts analysis (using the `-max_paths` parameter) to the specified number of N endpoints.

This attribute is valid for both EPBA as well as [infinite depth path-based analysis \(IPBA\)](#).

Note: When this attribute is enabled, there may be an increase in run time because the software will analyze all the violating endpoints and analysis will not be restricted to the specified N endpoints.

timing_path_based_exhaustive_max_paths_limit

timing_path_based_exhaustive_max_paths_limit *integer*

Default: 2000000

Data_type: Integer

Specifies the maximum number of paths that can be internally analyzed during exhaustive path-based analysis (PBA).

If the number of candidate paths during exhaustive PBA is greater than the specified max paths limit, then the software will skip path-based analysis of these paths beyond this limit. The paths exceeding the specified max paths limit will then be included as GBA in the final report output so that real violations are not missed.

timing_path_based_ipba_endpoints_max_limit

timing_path_based_ipba_endpoints_max_limit *integer*

Default: 100000

Data_type: Integer

Specifies the maximum number of worst critical GBA endpoints, which will be picked for IPBA analysis. The rest of the GBA endpoints will report GBA slack.

This attribute should be set to a number higher than the total number of GBA violating endpoints, in order to cover all the violating endpoints for IPBA.

To ensure that all the GBA violations are considered for IPBA analysis, the `report_timing -max_paths` parameter should be set equal to or greater than the total number of GBA violating endpoints.

timing_pba_exhaustive_path_nworst_limit

`timing_pba_exhaustive_path_nworst_limit <value>`

Default: 10000

Data_type: Integer

Specifies the maximum number of paths per endpoint (nworst) that will be re-timed in exhaustive path-based analysis (PBA).

In exhaustive PBA mode, the value specified with the `report_timing -nworst` parameter is used only during the final reporting. The value specified with the `timing_pba_exhaustive_path_nworst_limit` attribute (and not the `report_timing -nworst` value) is used to specify the maximum number of paths to be re-timed per endpoint.

If the limit specified by `timing_pba_exhaustive_path_nworst_limit` is reached and `timing_path_based_enable_exhaustive_depth_bounded_by_gba` attribute is set to:

- `true`: The worst of the current PBA slack is used and N+1th GBA path is reported.
- `false`: The current PBA slack is reported - which may be optimistic.

timing_path_based_report_analysis_summary_max_paths_limit

`timing_path_based_report_analysis_summary_max_paths_limit integer`

Default: 2000000

Data_type: Integer

Specifies the limit on the maximum paths that can be reported in PBA mode with the `report_analysis_summary` command.

timing_pll_clock_use_driving_cell

```
timing_pll_clock_use_driving_cell {true | false}
```

Default: false

Data_type: Boolean

Uses delay calculation of all the enabled arcs to the PLL clock output to compute the transition.

When set to `true`, the delay calculation of all enabled arcs to the PLL clock output will be used to compute the transition. If no driving arcs are available in the model or if they are disabled, the same idealized transition will be used.

When set to `false`, the software considers the PLL clock output to be electrically isolated from the input-side reference clock, and creates the output clock with an idealized transition. You can use the `set_annotated_transition` command to customize the output clock transition.

timing_prefix_module_name_with_library_generated_clock

```
timing_prefix_module_name_with_library_generated_clock {true | false}
```

Default: true

Data_type: Boolean

When set to `true`, the software appends the instance name to the clock pin name when creating a generated clock. When set to `false`, the software uses only the clock pin name when creating a generated clock.

For example, assume the cell for instance `a/b` in the timing library contained the following generated clock group:

```
generated_clock(genclk2) {  
  clock_pin : clk1;  
  master_pin : "int/clk";  
  multiplied_by : 2;  
  duty_cycle : 50.0;  
}
```

By default (`true`), the software creates a generated clock with the following name:

```
a/b/int/clk
```

If you set the attribute to `false`, the software creates a generated clock with the following name:

```
int/clk
```

If you set this attribute to `false`, and the `timing_library_generated_clock_use_group_name` attribute is

set to `true`, the software creates a generated clock with the following name:

`genclk2`

timing_propagate_latch_data_uncertainty

```
timing_propagate_latch_data_uncertainty {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, uses the clock phase associated with a flush latch's data pin as the "from" clock phase for downstream uncertainty timing calculations

When set to `false`, the downstream uncertainty calculations are based on the clock phase of the flush latch's clock signal.

timing_property_arrival_window_enable_tcl_dict_format

```
timing_property_arrival_window_enable_tcl_dict_format {true | false}
```

Default: `false`

Data_type: Boolean

Allows the software to print the new format of the `arrival_window` property (see [get_property](#) command).

timing_property_arrival_clocks_consider_clock_source_data_phase

```
timing_property_arrival_clocks_consider_clock_source_data_phase {true | false}
```

Default: `true`

Data_type: Boolean

Considers the clock source data phases.

The [get_property](#) and [report_property](#) commands support the `arrival_clocks` collection property on pin objects. The `arrival_clocks` property considers data phases, clock source data phases, and latency phases.

timing_property_arrival_clocks_consider_data_phase

```
timing_property_arrival_clocks_consider_data_phase {true | false}
```

Default: true

Data_type: Boolean

Returns the pure data phase.

The `get_property` and `report_property` commands support the `arrival_clocks` collection property on pin objects. The `arrival_clocks` property considers data phases, clock source data phases, and latency phases.

timing_property_arrival_clocks_consider_latency_phase

```
timing_property_arrival_clocks_consider_latency_phase {true | false}
```

Default: true

Data_type: Boolean

Returns the latency phase.

The `get_property` and `report_property` commands support the `arrival_clocks` collection property on pin objects. The `arrival_clocks` property considers data phases, clock source data phases, and latency phases.

timing_property_return_null_collection_with_quiet

```
timing_property_return_null_collection_with_quiet {true | false}
```

Default: false

Data_type: Boolean

Allows you to query values of all the properties.

When set to `true`, the software enables returning values of properties of all the objects, when the `get_property -quiet` parameter is specified.

timing_rail_swing_checks_high_voltage_threshold

```
timing_rail_swing_checks_high_voltage_threshold double
```

Default: 0.95

Data_type: Double

Specifies the voltage threshold values for high rail swing checks.

timing_rail_swing_checks_low_voltage_threshold

```
timing_rail_swing_checks_low_voltage_threshold double
```

Default: 0.05

Data_type: Double

Specifies the voltage threshold values for low rail swing checks.

timing_rcdb_allow_mismatch_option

```
timing_rcdb_allow_mismatch_option {true | false}
```

Default: true

Data_type: Boolean

Disables errors while reading boundary models.

When set to `true`, the software disables errors when reading the boundary model RCBD for cases where the contents do not match the boundary model netlist.

timing_recompute_sdf_in_setuphold_mode

```
timing_recompute_sdf_in_setuphold_mode {true | false}
```

Default: false

Data_type: Boolean

Controls the recomputing of SDF delays when the software is in simultaneous setup and hold analysis mode.

When the software is not in simultaneous setup and hold analysis mode, only one corner of data is stored at a time; therefore additional delay calculation is required for `write_sdf` command. When the software is in simultaneous setup and hold analysis mode, both sets of data are in memory at the same time, and additional delay calculation is not necessary.

If set to `false`, `write_sdf` will write out the delays from memory, instead of calling delay calculation.

Note: This attribute must be used with `timing_enable_simultaneous_setup_hold_mode true`.

timing_reduce_multi_drive_net_arcs

```
timing_reduce_multi_drive_net_arcs {true | false}
```

Default: true

Data_type: Boolean

Controls whether multi-drive or mesh networks are reduced to simpler, single driver models.

When set to `true`, the nets that meet the drivers' receivers arc threshold (defined using `timing_reduce_multi_drive_net_arcs_threshold` attribute), are reduced. The net arcs are created only from one driver or from the drivers for which you have set the constraints.

If you specify constraints on the net driven by parallel buffers, it might result in increased run time and memory degradation. By specifying timing constraints through nets, the constraints are moved to the drivers. This leads to the creation of net arcs from all the drivers, thus disabling net arc reduction. In such cases, you can select one driver of the net and use that driver to specify the constraints.

When set to `false`, the number of net arcs created for timing analysis for nets driven by parallel buffers are not reduced. If a net is driven by n parallel buffers and is connected to m sink pins, then the total number of net arcs created is $n*m$. For example, if n is 100 and m is 20000, the number of net arcs created for timing analysis will be two million. This may result in increased run time and memory usage.

timing_reduce_multi_drive_net_arcs_threshold

```
timing_reduce_multi_drive_net_arcs_threshold int
```

Default: 10000

Data_type: Integer

Sets a threshold number that is used to trigger the reduction of timing arcs of nets driven by parallel buffers. The reduction takes place if the number of arcs is greater than the threshold value and if the `timing_reduce_multi_drive_net_arcs` attribute is set to `true`.

timing_report_analysis_summary_csv_extended_new_format

```
timing_report_analysis_summary_csv_extended_new_format {true | false}
```

Default: false

Data_type: Boolean

Keeps the analysis summary CSV extended report in sync with the summary timing report. These reports are available when the respective `report_timing` parameters are specified:

- `-analysis_summary_csv_extended_file`
- `-analysis_summary_file`

When set to `true` (and when the `report_timing -analysis_summary_csv_extended_file` parameter is specified), the column name sequence will be from `fromClk` to `toClk`, that is, `fromClk` will be printed first, and then `toClk`. Also, the timing report will show "-", if `toClk` or `fromClk` is not present (and when `report_analysis_summary -expanded_summary_clocks` is set to `false`).

When set to `false`, the missing `toClk` or `fromClk` column will be represented as "*".

timing_report_arrival_property_worstcase_mode

`timing_report_arrival_property_worstcase_mode` *Integer*

Default: 0

Data_type: Integer

Differentiates the clock and data phases based on the `arrival_*` properties (see `get_property` command). The accepted values are 0, 1, 2, or 3.

timing_report_begin_end_pair_max_path_limit

`timing_report_begin_end_pair_max_path_limit` *integer*

Default: 2000000

Data_type: Integer

Sets a limit on the maximum number of paths that can be reported when the `report_timing -begin_end_pair` parameter is specified.

Note: Higher maximum paths limit may lead to high memory usage and runtime.

timing_report_check_timing_unconstrained_endpoints_due_to_constants

`timing_report_check_timing_unconstrained_endpoints_due_to_constants` {`true` | `false`}

Default: `false`

Data_type: Boolean

Enables the software to flag unconstrained signals arriving at the end points due to case analysis.

When set to `false`, the `check_timing` command output will show warnings for the unconstrained endpoints.

When set to `true`, the command output will also show warnings for unconstrained endpoints due to case analysis under the subcategory `uncons_endpoints_due_to_case_analysis`. For more details, see [check_timing](#).

timing_report_clock_pin_as_begin_point

```
timing_report_clock_pin_as_begin_point {true | false}
```

Default: `false`

Data_type: Boolean

Allows the software to report clock pins as begin points.

timing_report_constraint_extended_cell_em_flow

```
timing_report_constraint_extended_cell_em_flow {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, the software enables extended Cell EM flow.

timing_report_constraint_enable_extended_drv_format

```
timing_report_constraint_enable_extended_drv_format {true | false}
```

Default: `false`

Data_type: Boolean

Enables the software to report data as per clock/data and rise/fall phases.

timing_report_constraint_format

`timing_report_constraint_format string`

Default: ""

Data_type: String

Specifies the DRV fields that will be reported with the `report_constraint` command. For valid format column options, refer to `report_constraint -drv_fields`.

If DRV fields are not specified with this attribute (or with `report_constraint -drv_fields`), then the default set of DRV fields will be displayed. By default, the constraint report will display the pin names, the required and actual DRC values, and the view names.

Note: The reporting fields specified with the `report_constraint -drv_fields` parameter will override the attribute settings.

timing_report_constraint_rise_fall_clock_period_check

`timing_report_constraint_rise_fall_clock_period_check {true | false}`

Default: false

Data_type: Boolean

Enables reporting of rise-to-rise and fall-to-fall clock period checks separately for the `report_constraint` command.

When set to `false`, the software reports the rise-to-rise and fall-to-fall clock period checks under the same table in the report. With the `false` setting, when the `report_constraint -check_type clock_period` option is specified, the software reports violations that are the worst amongst all the rise-fall transitions for each point.

timing_report_constraint_report_all_drv_violation

`timing_report_constraint_report_all_drv_violation {true | false}`

Default: true

Data_type: Boolean

Enables reporting of all the design rule violations (DRV).

When set to `false`, the software reports the worst 1000 DRV violations per DRV check (specified with the `report_constraint -all_violators -drv_violation_type` command).

When set to `true`, the software will report all the DRV violations. You can use the `report_constraint -max_pins_per_drv` parameter to specify the maximum number of DRV violations to be reported.

Note: The `-max_pins_per_drv` parameter has higher precedence over the `timing_report_constraint_report_all_drv_violation` attribute setting.

timing_report_constraint_use_infinity_slack_for_unconstrained

```
timing_report_constraint_use_infinity_slack_for_unconstrained {true | false}
```

Default: `false`

Data_type: Boolean

Reports the timing slacks of unconstrained paths through the DRV violating pin as “INFINITY”. By default, slacks of unconstrained paths are reported as * (asterisk).

timing_report_default_frequency_for_unconstrained_nets

```
timing_report_default_frequency_for_unconstrained_nets value
```

Default: `1e+09`

Defines the frequency for unconstrained nets to be used in maximum capacitance DRV reporting.

timing_report_disable_max_paths_per_group

```
timing_report_disable_max_paths_per_group {true | false}
```

Default: `false`

Data_type: Boolean

Controls the interpretation of the `report_timing -max_paths` parameter when you request reporting across a set of path groups. By default (`false` setting), the specified `-max_paths` will be reported per path group. With the `true` setting, a total of the specified `-max_paths` will be reported across all of the specified path groups.

For Stylus flow cross-tool compatibility – you should specify a setting of `true`. For backward compatibility with the legacy UI flow – you should use a value of `false`.

For example,

When set to `false`:

Legacy UI: `report_timing -path_group {reg2reg in2reg} -nworst 2 ...`

Stylus UI: `report_timing -group {reg2reg in2reg} -nworst 2 ...`

The `report_timing` command will return up to 2 paths for the `reg2reg` group and also up to 2 paths for the `in2reg` group.

When set to `true`:

Legacy UI: `set timing_report_disable_max_paths_per_group true`

Stylus UI: `set_db timing_report_disable_max_paths_per_group true`

A total of 2 paths will be reported across both path groups. The paths may come entirely from one or the other group – or both, based on the slack value.

timing_report_drv_enable_clock_source_as_clock

`timing_report_drv_enable_clock_source_as_clock {true | false}`

Default: `false`

Data_type: Boolean

Enables the clock DRV for pure clock source path instead of data DRV.

timing_report_drv_enable_frequency_per_view

`timing_report_drv_enable_frequency_per_view {true | false}`

Default: `true`

Data_type: Boolean

Enables view-based frequency DRV flow.

When set to `true`, in the MMMC DRV flow, the software performs frequency computation for design pins as per the clock period of specific analysis views reaching a pin. In case of non-activity based flow, the frequency is computed as per the fastest clock of all the views.

When set to `false`, in the propagate activity flow, the software performs frequency computation for design pins from propagated activity on that pin.

For other flows, the software performs frequency computation for design pins as per the smallest clock period (largest clock frequency) from all the active analysis views.

timing_report_drv_per_frequency_per_input_slew

`timing_report_drv_per_frequency_per_input_slew {true | false}`

Default: false

Data_type: Boolean

Enables frequency dependent DRV lookup from a library.

When set to `true`, the software will enable the `report_constraint` command to honor `max_transition` or `max_capacitance` limit after worst-casing due to the following cases:

- One-dimensional frequency DRV commands, such as, `set_max_transition_per_freq` or `set_max_cap_per_freq`.
- Two-dimensional maximum transition or capacitance frequency/electro-migration tables.
- Other frequency independent DRV limit sources, e.g., `set_max_transition` from the SDC or library limit.

timing_report_drv_enable_ghz_notation_for_drv_fields

```
timing_report_drv_enable_ghz_notation_for_drv_fields {true | false}
```

Default: false

Data_type: Boolean

Enables reporting of clock frequency in GigaHertz (Ghz). The default frequency unit is MegaHertz (MHz).

timing_report_drv_enable_slew_threshold_scaling

```
timing_report_drv_enable_slew_threshold_scaling {true | false}
```

Default: false

Data_type: Boolean

Enables the transition constraints scaling as per the slew threshold value.

timing_report_drv_per_frequency

```
timing_report_drv_per_frequency  
{true | false}
```

Default: true

Data_type: Boolean

Improves reporting of maximum transition violations as per the worst limit defined using the `set_max_transition` and `set_max_transition_per_freq` commands, or the library specifications. This behavior applies to minimum/maximum transition and capacitance limits.

In MMMC designs, for reporting transition and capacitance violations, the software uses the worst transition limit specified in the transition limit sources, for example, library specifications, or `set_max_transition` constraints.

For frequency-based transition specifications, the transition violations are reported only on the basis of the transition limit specified with frequency-based specifications. The `set_max_transition` specifications are ignored by the software, if the values are pessimistic.

timing_report_drv_use_worst_timing_slack

```
timing_report_drv_use_worst_timing_slack  
{true | false}
```

Default: false

Data_type: Boolean

Enables reporting of the worst DRV slack across all the views for configurable DRV report.

When set to `true`, the software shows a non-default special case report, where timing slacks for MMMC flow is the worst among all active views.

timing_report_enable_cppr_point

```
timing_report_enable_cppr_point { true | false}
```

Default: false

Data_type: Boolean

Enables the timing report to output CPPR point details.

When set to `true`, the `report_timing` command output shows the CPPR point field.

timing_report_enable_em_index_clipping_report

```
timing_report_enable_em_index_clipping_report {true | false}
```

Default: false

Data_type: Boolean

Enables index clipping reporting for EM (electro-migration) DRV (design rule violation) reports.
For more information, refer to the [Cell EM Analysis and ECO](#) chapter in the *Tempus Stylus User Guide*.

timing_report_enable_flag_field_symbols

```
timing_report_enable_flag_field_symbols {true | false}
```

Default: false

Data_type: Boolean

Enables reporting of Instance/Net related bits in the [report_timing](#) Flags column.

timing_report_enable_clock_to_for_unconstrained_paths

```
timing_report_enable_clock_to_for_unconstrained_paths {true | false}
```

Default: false

Data_type: Boolean

Enables unconstrained path reporting when the [report_timing -clock_to](#) parameter is specified.

timing_report_enable_lead_trail_to_rise_fall_map

```
timing_report_enable_lead_trail_to_rise_fall_map {true | false}
```

Default: false

Data_type: Boolean

Enables reporting of rise/fall edge times, instead of lead/trail edge times of a clock (reported using the [report_clocks](#) command).

timing_report_enable_markers

```
timing_report_enable_markers{true | false}
```

Default: true

Data_type: Boolean

Enables display of markers in reports.

When set to `true`, the `report_timing` output format displays markers that identify pins specified using the `-from`, `-to`, or `-through` parameters. The markers, displayed as ‘->’, show up in the ‘timing point’ or ‘hpin’ column (if the ‘timing point’ column is not available) of the timing report. This feature provides better readability. When set to `false`, the timing report does not display the markers.

timing_report_enable_max_capacitance_drv_for_constant_nets

```
timing_report_enable_max_capacitance_drv_for_constant_nets {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, this attribute will perform max_capacitance design rule violation check on constant elements as well.

timing_report_enable_max_path_limit_warning

```
timing_report_enable_max_path_limit_warning {true | false}
```

Default: `false`

Data_type: Boolean

Determines if the number of reported paths for a particular clock group equals the specified maximum paths limit.

When set to `true`, the software will issue a warning message in case the number of reported paths for a clock group is equal to the given maximum paths limit. This applies to both graph- and path-based reporting modes.

This attribute is supported in clock group-based non-statistical reporting flows only. The clock group-based reporting mode can be enabled by setting `timing_report_group_based_mode` attribute to `true`.

timing_report_enable_qpin_as_start_for_begin_end_pair

```
timing_report_enable_qpin_as_start_for_begin_end_pair  
{true | false}
```

Default: `false`

Data_type: Boolean

Enables reporting of multiple paths with different q-pins having the same clock pin.

timing_report_enable_report_clock_timing_across_clock_pin

```
timing_report_enable_report_clock_timing_across_clock_pin {true | false}
```

Default: false

Data_type: Boolean

Enables fanout tracing across clock pins if any combinational arc is present.

timing_report_enable_si_debug

```
timing_report_enable_si_debug {true | false}
```

Default: false

Data_type: Boolean

Allows the software to capture signal integrity (SI) related details for each stage of a path being analyzed during path-based analysis in the form of attributes.

timing_report_enable_verbose_ssta_mode

```
timing_report_enable_verbose_ssta_mode {true | false}
```

Default: false

Data_type: Boolean

Enables reporting of sigma/multiplier for the timing report ([report_timing](#) command) header section in SSTA or SOCV mode.

timing_report_enable_unique_pins_multiple_capture_clock_paths

```
timing_report_enable_unique_pins_multiple_capture_clock_paths {true | false}
```

Default: false

Data_type: Boolean

Enables reporting of different paths with respect to the reference clocks in the unique pins.

timing_report_enable_write_twf_third_party_for_input_pins

```
timing_report_enable_write_twf_third_party_for_input_pins {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software writes timing information for input pins in the third-party TWF file.

timing_report_fields

```
timing_report_fields string
```

Default: {instance arc cell delay arrival required}

Data_type: String

Specifies a `report_timing` format. See `report_timing -fields` for more information.

Valid format columns are:

adjustment, abs_delay_err, abs_transition_err, annotation, aocv_adj_stages, aocv_derate, aocv_weight, arc, arrival, arrival_mean, arrival_sigma, cell, delay, delay_mean, delay_sigma, direction, edge, fanin, fanout, flags, hpin, incr_delay, instance, instance_location, latch_window, load, module, net, pct_delay_err, pct_slew_err, phase, phys_info, pin, pin_load, pin_location, power_domain, required, retime_delay, retime_delay_mean, retime_delay_sigma, retime_mis_delta, retime_slew, retime_transition_mean, retime_transition_sigma, stage_count, transition, transition_mean, transition_sigma, socv_derate, spice_arrival, spice_delay, spice_slew, stolen, timing_point, total_derate, user_derate, voltage, vt_skew_derate, when_cond, wire_load, wlmodel

timing_report_generated_clock_info

```
timing_report_generated_clock_info {true | false}
```

Default: true

Data_type: Boolean

When set to `true` (the default), generated clock information is automatically added to the report if generated clocks are encountered in either the launching or latching clock paths. The generated clock information column is displayed if the 'Delay' field exists. If the 'Delay' field does not exist, then the generated clock adjustment column is added to the report only when explicitly specified using the `report_timing -fields` command.

timing_report_group_based_mode

```
timing_report_group_based_mode {true | false}
```

Default: `false`

Data_type: Boolean

Groups paths by clock domain.

When set to `true`, the behavior of the following reporting commands will change as follows:

report_timing

The behavior of the following `report_timing` parameters changes as follows:

- `-max_points`: In this mode you are not required to specify this parameter. If specified, the parameter is mapped to `-max_paths` option.
- `-max_paths M`: Reports `M` paths per clock group.
- `-nworst N`: Limits the number of paths per endpoint per clock group. By default, the value of `-nworst` is 1.

The `report_timing` command will have the following four types of groups (if design does not have user-defined path groups):

- Asynch group: Recovery/removal checks.
- Clock gating group: Inferred and library clock gating checks.
- Default group: Combinational max delay or min delay paths.
- Clock Groups: Groups for all design clocks. For a design with three clocks, three groups will be reported, one group for each clock. Endpoints sharing the same reference clock will be part of the same group. If an endpoint belongs to multiple groups then it will be reported separately in each group.

Note: If user-defined path groups are specified, the software will override the path groups described above.

`report_min_pulse_width`

The `report_min_pulse_width` command reports pulse width slacks of all the clocks for a pin. In summary mode, the "clock" column will be displayed. In verbose mode (with `path_type` option), the behavior will be similar to the `report_timing` output in group-based mode.

report_constraint

The `report_constraint` command will report the following checks:

- For max_delay/setup and min_delay/hold type checks paths will be reported for each clock group separately.
- The behavior of pulse width check types will be the same as `report_min_pulse_width` command.

report_analysis_coverage

The `report_analysis_coverage` command will report a check at end points for all the clocks. In verbose mode, the "clock" column will be displayed.

timing_report_limit_max_path_count

`timing_report_limit_max_path_count value`

Default: 2000000

Data_type: integer

Sets the maximum number of violations (of data/clock checks) to be reported.

timing_report_max_transition_check_using_nsigma_slew

`timing_report_max_transition_check_using_nsigma_slew {true | false}`

Default: false

Data_type: Boolean

Enables the `report_constraint` command to use mean and sigma slew values for reporting transition values in DRV checks.

When set to `true`, in the SOCV flow the `report_constraint` command uses the mean plus n-sigma slew values for DRV checks.

When set to `false`, the `report_constraint` command will report only the mean slews.

timing_report_precision

`timing_report_precision integer`

Default: 3

Data_type: Integer

Controls the number of digits appearing after the decimal point in the `report_timing`, `report_nets`, `report_cell_instance_timing`, and `report_clocks` reports.

timing_report_property_fastest_clock_consider_data_phase

`timing_report_property_fastest_clock_consider_data_phase`

`{true | false}`

Default: false

Data_type: Boolean

Considers the data signals while determining the fastest clock arriving on any given pin.

When set to `false`, the clocks arriving in clock phase form will be considered for determining the fastest clock.

When set to `true`, the clocks arriving in clock phase as well as data phase form will be considered.

timing_report_pulse_width_matching_launch_capture_paths

`timing_report_pulse_width_matching_launch_capture_paths {true | false}`

Default: false

Data_type: Boolean

Reports pulse width paths that have matching launch and capture paths - the count of pins and the pins must match exactly. The paths that do not meet this condition will not be reported.

When set to `true`, the software will impact the minimum pulse width report that is generated with the `report_min_pulse_width` command along with the `-path_type short` and `-path_type full_clock` options.

timing_report_redirect_message_types

```
timing_report_redirect_message_types  
{none | info}
```

Default: none

Data_type: Enum

Redirects reporting messages to a report file.

When set to `info`, the path count and max depth (displayed when the `report_timing` command is run in PBA mode) will be appended to the final report output.

When set to `none`, the reporting messages are not redirected to a report file.

timing_report_retime_formatting_mode

```
timing_report_retime_formatting_mode {manual | retime_compare | retime_replace}
```

Default: manual

Data_type: Enum

Manages the re-timing fields in the reporting format. Based on the given settings, this attribute automatically replaces (or adds) the default columns with the respective re-timing columns. For example, in case of delay column, 'Retime Delay' will be added or replaced automatically.

timing_report_skip_constraint_loop_check

```
timing_report_skip_constraint_loop_check {true | false}
```

Default: true

Data_type: Boolean

Allows you to skip loop checking when the `check_timing` command is used.

When set to `true`, the software skips reporting of loops in case the timing graph inside a loop is broken. This may happen if some of the commands, such as, `create_clock`, `set_input_delay`, or `set_output_delay` are defined inside a loop.

Note: When this attribute is set to `true`, the `check_timing` command will report lesser loops than the ones reported in the CTE_loops.rpt report - which reports all the loops.

timing_report_skip_icg_from_all_fanin_fanout_collection

```
timing_report_skip_icg_from_all_fanin_fanout_collection {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the software skips ICG clock pins from the `all_fanin` (or `all_fanout`) command collection, when queried with startpoints/endpoints.

timing_report_socv_summary_mean_sigma

```
timing_report_socv_summary_mean_sigma {true | false}
```

Default: false

Data_type: Boolean

Prints the report header in new format when the `report_timing` command is run in SOCV mode. The new header contains nsigma, mean, and sigma details.

timing_report_timing_header_detail_info

```
timing_report_timing_header_detail_info {default | extended}
```

Default: default

Data_type: Enum

Controls the timing report (generated using the `report_timing` command) header format. You can specify one of the following options:

- When set to `default`, the software generates timing reports with a report header that includes the following information:
 - Tempus software version number
 - Platform on which the software is being run
 - Time when the report was generated
 - Command used to generate the report
- When set to `extended`, the software generates timing reports with additional header information

given below:

- The analysis mode - best case worst case or on chip variation
- The active views (displayed only in MMMC mode)
- The clock reconvergence pessimism (CPPR)
- The latch slack mode
- The specified clock propagation value
- The specified delay calculation engine

Note: You can use this attribute when `timing_disable_report_header_info` is set to `false`.

timing_report_unconstrained_paths

```
timing_report_unconstrained_paths {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, the `report_timing` command reports unconstrained paths if the software cannot find any constrained paths to report.

When set to `false`, the `report_timing` command reports only the constrained paths.

Note: The behavior of `timing_report_unconstrained_paths` attribute is not the same as the behavior of `report_timing -unconstrained` command. If there are several paths to the same endpoint from different begin points, including constrained and unconstrained paths, the `report_timing -unconstrained` parameter always reports unconstrained paths, even if a constrained path can be reported. Whereas the `timing_report_unconstrained_paths` attribute reports constrained paths but not unconstrained paths.

timing_report_unconstrained_path_early_late_header

```
timing_report_unconstrained_path_early_late_header {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, this software provides information in the timing report header that indicates whether an unconstrained path is a late or early path.

timing_report_use_receiver_model_capacitance

```
timing_report_use_receiver_model_capacitance {true | false}
```

Default: false

Data_type: Boolean

Enables the max_capacitance violations based on dynamic pin capacitance.

When set to `true`, the software checks for both the input level and timing arc level dynamic pin capacitance tables for worst-case pin capacitance table for given input slew. If conditional pin capacitance tables (or timing_arcs) exist, the worst-case is used among all the conditions.

This attribute performs static pin capacitance inference after delay calculation, so the delay computation is not impacted. The pin capacitance is used only for reporting and max_cap violations.

timing_report_use_worst_parallel_cell_arc

```
timing_report_use_worst_parallel_cell_arc {true | false}
```

Default: false

Data_type: Boolean

When set to `false`, setting the `-nworst` parameter reports several paths by selecting parallel arcs in the library cell between two pins.

When set to `true`, only a single worst path is reported by selecting the worst delay arc among all parallel arcs of a cell. For example, for reporting timing through A to Y pins (where the cell is a 2-input cell), the parallel arc is applicable for the same input and output pin. So the worst arc for A->Y is chosen from all arcs of A->Y.

timing_resolve_driver_conflicts

```
timing_resolve_driver_conflicts {conservative | aggressive}
```

Default: aggressive

Data_type: Enum

Resolves constant propagation results on nets with multiple drivers.

When the attribute is set to `conservative` mode, the net values are as follows:

- If all the drivers are 1, the net will be driven to value 1

- If all the drivers are 0, the net will be driven to value 0
- In other cases, the net value will be `Undefined`

When the attribute is set to `aggressive` mode, the net values are as follows:

- If some of the drivers are 0, the net value will be 0
- If some of the drivers are 1, but none are 0, then the net value will be 1
- In other cases, the net value will be `Undefined`

timing_scaling_for_negative_checks

```
timing_scaling_for_negative_checks {default | divider | multiplier}
```

Default: default

Data_type: Enum

Modifies the scaling of the negative timing analysis check value. This variable does not affect the positive checks. You can specify the following options:

- `default`: Negative check is multiplied by (2.0 - derating factor), where the derating factor is the value that you set using the `set_timing_derate` command.
- `divider`: Divides the negative check value by the derating factor.
- `multiplier`: Multiplies the negative check value by the derating factor.

timing_scaling_for_negative_delays

```
timing_scaling_for_negative_delays {default | divider | multiplier}
```

Default: default

Data_type: Enum

Modifies the scaling of the negative delay value to be used during timing analysis. This attribute does not affect the positive delay. You can specify the following options:

- `default`: The negative delay is multiplied by (2.0 - derating factor), where the derating factor is the value that you set using the `set_timing_derate` command.
- `divider`: The software divides the negative delay value by the derating factor.
- `multiplier`: The negative delay value is multiplied by the derating factor.

Currently, the constraints are used during timing in the flattened mode, so the internal ILM instances are seen instead of the LEF pins of the ILMs. Therefore, reading the bounding box constraints can cause errors without this variable set. If you want to see the LEF pins of the ILM in GUI, the design must be in the unflattened mode.

timing_sdf_adjust_negative_setuphold

```
timing_sdf_adjust_negative_setuphold {true | false}
```

Default: false

Data_type: Boolean

Controls how the setup and hold check values are adjusted when both are initially negative in the SDF file.

When set to `true`, the software sets the smaller check delay value to a negated larger check delay value. For example, if the initial setup/hold value is equal to -1/-2. then the value -2 from the setup is smaller and it is reset to a negated value of the larger one (-1 from hold). So the adjusted setup/hold value is equal to -1/1.

When set to `false`, both the negative setup and hold check values are set to 0.

The command order for using this attribute is as follows:

- `read_sdf`
- `timing_sdf_adjust_negative_setuphold {true | false}`
- `write_sdf`

The timing report (`report_timing`) results are not impacted.

timing_sdf_enable_setuphold_scond_ccond

```
timing_sdf_enable_setuphold_scond_ccond {true | false}
```

Default: false

Data_type: Boolean

When set to `true`, enables proper generation of SDF (Standard Delay Format) with `scond` and `ccond` qualifiers on `SETUPHOLD` and `RECREM` timing checks.

Since some SDF readers do not accept `scond` and `ccond` qualifiers this attribute is set to `false` by default.

timing_self_loop_paths_no_skew_max_depth

`timing_self_loop_paths_no_skew_max_depth int`

Default: 10

Data_type: Integer

Identifies self-loop paths at the specified depth.

For example:

```
set_db timing_self_loop_paths_no_skew_max_depth 20
```

Allows the timer traverse 20 timing arcs (10 stages of logic) before abandoning the search for a self loop.

timing_self_loop_paths_no_skew_max_slack

`timing_self_loop_paths_no_skew_max_slack value`

Default: 0.0

Data_type: Double

Identifies self-loop paths at the specified threshold.

For example:

```
set_db timing_self_loop_paths_no_skew_max_slack 1.0
```

In this case, all timing endpoints with a worst slack less than 1.0 are considered for self loop skew removal.

timing_set_clock_source_to_output_as_data

`timing_set_clock_source_to_output_as_data {true | false}`

Default: false

Data_type: Boolean

When set to `true`, causes a clock source path leading to an output or bidi port to be treated as a data path if there is `set_output_delay` or `set_data_check` assertion on the port.

timing_socv_preserve_variation_with_annotations

timing_socv_preserve_variation_with_annotations {true | false}

Default: false

Data_type: Boolean

Preserves the sigma value computed by delay calculation along with the annotation from SDC.

In the clock mesh flow, it is possible to preserve sigma values even after applying annotation on slew/delay through SDC.

When this attribute is set to `true`, the software accepts the sigma value computed by delay calculation (for nets that have delay/slew annotations from SDC, e.g., clock-mesh), along with the annotation from SDC.

timing_socv_rc_variation_mode

timing_socv_rc_variation_mode {true | false}

Default: true

Data_type: Boolean

Enables interconnect variation mode in SOCV mode.

timing_socv_sigma_spatial_multiplier

timing_socv_sigma_spatial_multiplier {true | false}

Default: 1.0

Data_type: Double

Provides a fractional percentage multiplier, which allows you to select some (or all, none) of the spatial derate to be applied.

timing_socv_view_based_nsigma_multiplier_mode

```
timing_socv_view_based_nsigma_multiplier_mode {true | false}
```

Default: true

Data_type: Boolean

Enables setting of view-based separate setup and hold sigma multipliers.

By default or with an explicit true setting, the timing system is configured to support different N-sigma multiplier values for Setup vs. Hold – and for different analysis views. The specific N-sigma multipliers can be set using the `set_socv_reporting_nsigma_multiplier` command.

timing_spatial_derate_chip_size

```
timing_spatial_derate_chip_size value_in_microns
```

Default: 1e+30

Data_type: Double

Allows you to define the chip size.

The chip size is the diagonal length of a rectangle that is formed by the chip's length and width. You can obtain the diagonal distance by calculating the square-root of the $\text{Length}^2 + \text{Width}^2$. The diagonal distance should always be specified in units of microns.

The chip size can be picked in the following ways (in order of highest to lowest precedence):

- When set to a value other than 1e+30, the specified value will have the highest precedence.
- If the physical floorplan information is available, the chip size will be derived automatically from the floorplan.
- If the SPEF parasitic files containing the coordinate information are loaded, then the chip size will be automatically derived.

timing_spatial_derate_distance_mode

```
timing_spatial_derate_distance_mode {chip_size | arc_bounding_box}
```

Default: chip_size

Data_type: Enum

Allows you to select the spatial mode. You can specify one of the following options:

- `chip_size`: Uses graph-based analysis (GBA) spatial mode.
- `arc_bounding_box`: When specified, the software reduces GBA spatial derate pessimism by limiting bounding box calculations only to all the timing paths through an instance. Reduced GBA-PBA gap and GBA pessimism results in improved PBA runtime. You can use the `arc_bounding_box` option when the `timing_enable_pessimistic_cppr_for_reconvergent_clock_paths` global variable is set to `true`.

Note: The spatial derate mode can be controlled using the `timing_enable_spatial_derate_mode` attribute. By default, this attribute is set to `true`.

This attribute can be used when the spatial derate mode is enabled using the `timing_enable_spatial_derate_mode true` setting.

timing_suppress_escape_characters

```
timing_suppress_escape_characters {true | false}
```

Default: `true`

Data_type: Boolean

Suppresses the reporting of escape characters in timing object names.

When the attribute is set to `true`, all the reporting and collection commands report the timing objects names (e.g., pins, ports, or instances) without the escape characters.

timing_suppress_ilm_constraint_mismatches

```
timing_suppress_ilm_constraint_mismatches {true | false}
```

Default: `false`

Data_type: Boolean

When set to `true`, the software suppresses all error and warning messages related to objects not found when loading SDC constraint files for the ILM flow.

In the current ILM flow, SDC constraints originally specified against the complete flat netlist for the design do not get filtered when being applied against the ILM view of the design. Constraints that reference parts of the design that were pruned cause warnings and errors during constraint loading.

timing_time_unit

`timing_time_unit` *string*

Default: none

Data_type: String

Specifies the timing units to be used for timing constraints and timing reports. The default units for timing are inferred from the timing libraries. You can override this inference by explicitly setting the value to `none`, `1ns`, `1ps`, `10ps`, or `100ps`. Setting this variable explicitly is the same as executing the `set_library_unit -time` command to set the time units.

timing_use_clock_pin_attribute_for_clock_net_marking

`timing_use_clock_pin_attribute_for_clock_net_marking` {true | false}

Default: false

Data_type: Boolean

Allows the propagation of clocks to pins with clock attributes regardless of the presence of check arcs or trigger arcs at the pins.

timing_use_latch_early_launch_edge

`timing_use_latch_early_launch_edge` {true | false}

Default: true

Data_type: Boolean

Enables the latch use early launch edge feature.

During timing analysis when time borrowing and clock path pessimism removal (CPPR) is enabled, the given time is calculated using both borrow time and CPPR time. This may result in unnecessary timing violations. Since CPPR is an accurate means of pessimism removal, you are required to set the `timing_use_latch_early_launch_edge` attribute to `false` so that CPPR is applied to all the paths in the design.

When set to `true`, the launch clock path of timing paths starting at a latch is timed in early mode for setup analysis, and for late mode for hold analysis. No CPPR credit is given to the timing path.

When set to `false`, the behavior is like for any other path. The launch clock path of timing paths starting at a latch is timed in late mode for setup analysis, and early mode for hold analysis. The CPPR credit is

given to the path according to the attribute CPPR settings.

timing_use_incremental_si_transition

```
timing_use_incremental_si_transition {true | false}
```

Default: false

Data_type: Boolean

Enables usage of incremental slew during DRV violation reporting.

timing_use_latch_time_borrow

```
timing_use_latch_time_borrow {true | false}
```

Default: true

Data_type: Boolean

When set to `false`, does not consider time borrowing during timing analysis. Time borrowing is the amount of time borrowed by a previous logic.

timing_use_verilog_for_model_netlist

```
timing_use_verilog_for_model_netlist int
```

Default: 0

Data_type: integer

Allows you to choose whether to write the scope and boundary model netlists in Verilog format instead of binary.

When set to 1, the software will use Verilog format for saving model nets.

timing_waveform_aware_pulse_width_checks_high_voltage_level

```
timing_waveform_aware_pulse_width_checks_high_voltage_level double
```

Default: 0.95

Data_type: Double

Specifies the high voltage level to be used for waveform-aware pulse width checks.

timing_waveform_aware_pulse_width_checks_low_voltage_level

```
timing_waveform_aware_pulse_width_checks_low_voltage_level double
```

Default: 0.05

Data_type: Double

Specifies the low voltage level to be used for waveform-aware pulse width checks.

timing_write_sdf_no_escape_backslash

```
timing_write_sdf_no_escape_backslash {true | false}
```

Default: false

Data_type: Boolean

Supports various patterns of the escape character.

For example, consider the following input Verilog expression:

```
\a/b\c\d
```

When the attribute is set to `true`, the `write_sdf` command removes the first escape character and outputs `a/b\c\d` in the SDF file.

When set to `false`, the command removes all the escape characters and outputs `a/b/c/d`.

update_analysis_view

```
update_analysis_view  
[-help]  
-name existingAnalysisViewName  
{[-constraint_mode newModeName]  
[-delay_corner newDelayCornerObj]  
[-latency_file string]  
[-power_modes powerModesList]}
```

Updates the attribute values of the specified existing analysis view.

i You can update an analysis view before the multi-mode multi-corner definition file is loaded into the design, or after. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode results in the timing, delay calculation, and RC data being reset.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-constraint_mode <i>newModeName</i></code>	Specifies the name of the new constraint mode to associate with this analysis view.
<code>-delay_corner <i>newDelayCornerObj</i></code>	Specifies the name of the new delay calculation corner to associate with this analysis view.
<code>-latency_file <i>string</i></code>	Specifies the latency file name.
<code>-name <i>existingAnalysisViewName</i></code>	Specifies the name of the existing analysis view to update.
<code>-power_modes <i>powerModesList</i></code>	Specifies list of power modes to use with this view. The modes must exist in the power intent file.

Examples

- The following command creates an analysis view called `missionSlow` using the constraint mode `missionSetup` and the delay calculation corner `dcWCCOM`:

```
tempus> create_analysis_view
-name missionSlow
-constraint_mode missionSetup
-delay_corner dcWCCOM
```

The following command changes the delay calculation corner associated with the analysis view `missionSlow` to `dcMax`:

```
tempus> update_analysis_view -name missionSlow -delay_corner dcMax
```

Related Commands

- `create_analysis_view`
- `set_analysis_view`

update_constraint_mode

```
update_constraint_mode
[-help]
[-name modeName]
{[[-sdc_files {file1.sdc file2.sdc ...}]
[-ilm_sdc_files {file1.sdc file2.sdc ...}]
[-tcl_variables {{var_name1 value1} {var_name2 value2} {var_name3 value3} ...}]
[-reset_latency_files ]] }
```

Updates the SDC constraint file information for the specified existing constraint mode object.

Note: The `update_constraint_mode` command overwrites the previous constraint mode settings. However, by default, this command updates a constraint mode without affecting other constraint modes, including interactive constraints, such as, `set_dont_use` and `set_dont_touch`.

 You can update a constraint mode object before the multi-mode multi-corner definition file is loaded into the design, or after. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode results in the timing, delay calculation, and RC data being reset.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-ilm_sdc_files {file1.sdc file2.sdc ...}</code>	Specifies the new SDC constraint files for the ILM flow to associate with this constraint mode.
<code>-name modeName</code>	Specifies the name of the existing constraint mode object to update.
<code>-reset_latency_files</code>	Cleans up latency files of all related views.
<code>-sdc_files {file1.sdc file2.sdc ...}</code>	Specifies the new SDC constraint files to associate with this constraint mode.
<code>-tcl_variables {{var_name1 value1} {var_name2 value2} {var_name3 value3} ...}</code>	Specifies a list of TCL variables and values to be used in the constraint mode.

Examples

- The following command groups the SDC files `io.sdc`, `mission1-clks.sdc`, and `mission1-except.sdc` to create a mode object named `missionSetup`:

```
tempus> create_constraint_mode -name missionSetup  
-sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc]
```

The following command changes the SDC files associated with the constraint mode `missionSetup` to `io.sdc`, `mission3-clks.sdc`, and `mission3-except.sdc`:

```
tempus> update_constraint_mode -name missionSetup  
-sdc_files {io.sdc mission3-clks.sdc mission3-except.sdc}
```

Related Commands

- `create_constraint_mode`

update_delay_corner

```
update_delay_corner  
[-help]  
-name delayCornerName  
[-early_estimated_worst_irDrop_factor percent]  
[-early_irdrop_data files_or_directories]  
[-early_irdrop_files list_of_files]  
[-early_rc_corner rcCornerObj]  
[-early_temperature_files list_of_files]  
[-early_timing_condition conditional_pairs]  
[-late_irdrop_data files_or_directories]  
[-late_irdrop_files list_of_files]  
[-late_rc_corner rcCornerObj]  
[-late_temperature_files list_of_files]  
[-late_timing_condition conditional_pairs]  
[-late_estimated_worst_irDrop_factor percent]  
[-irdrop_data files_or_directories]  
[-irdrop_files list_of_files]  
[-pg_net_voltages voltage_pairs]  
[-rc_corner rcCornerObj]  
[-si_enabled {true | false}]  
[-temperature_files list_of_files]  
[-timing_condition conditional_pairs]
```

Modifies the parameters of an existing delay calculation corner object. You can use the `update_delay_corner` command to add or change attribute values for an existing delay calculation corner object, or for an existing power domain definition.

You can update a delay calculation corner object before the multi-mode multi-corner definition file is loaded into the design, or after. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode results in the timing, delay calculation, and RC data being reset.

You also can use the `update_delay_corner` command to add a power domain definition to the specified delay calculation corner. Instances contained within an MSMV power domain often require a different library or operating condition that used for the default power domain. Power domain definitions within a delay calculation corner object can be used to assign specific libraries and PVT settings per power domain.

Note: Use separate delay calculation corners to define major PVT corner differences. Use the `-early_*` and `-late_*` parameters within a single delay calculation corner to control on-chip-variation.

The `-early_*` and `-late_*` parameters can be specified separately, to update a delay corner object with early or late information. If you only specify one of the `-early_*` or `-late_*` parameters, the software uses the original information pointer in place of the missing early/late parameter.

For example, if you initially created a delay corner object using:

```
create_delay_corner
-library_set libsNominal
...
```

Use this command after creating at least one delay calculation corner ([create_delay_corner](#)).

Parameters

<code>-help</code>	Prints out the command usage.
<code>-early_estimated_worst_irDrop_factor percent</code>	Specifies the early voltage derating factor. When this parameter is specified, the software performs delay calculations using the voltage = $\text{nomVolt} * (1 - \text{value})$. <i>Default: 0.0</i>
<code>-early_irdrop_data files_or_directories</code>	Specifies the IR drop files or directories to apply when calculating the early arrival times at a single delay corner.
<code>-early_irdrop_files list_of_files</code>	Specifies the list of IR drop files to apply when calculating early arrival times at a single power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. Note: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
<code>-early_rc_corner rcCornerObj</code>	Specifies the RC corner object to associate with the early corner object.
<code>-early_temperature_files list_of_files</code>	Specifies the name of the temperature file for temperature aware delay calculation for early corner.
<code>-early_timing_condition conditional_pairs</code>	Specifies pair list of domains/supply sets and timing conditions to associate with this delay corner object.
<code>-irdrop_data files_or_directories</code>	Specifies the IR drop files or directories to apply to both the early and late delay calculation for the specified delay corner object.

<code>-irdrop_files list_of_files</code>	Specifies the list of IR drop files to apply to both early and late delay calculation for this power domain object. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes. Note: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
<code>-late_estimated_worst_irDrop_factor percent</code>	Specifies the late voltage derating factor. When this parameter is specified, the software performs delay calculations using the voltage = $\text{nomVolt} * (1 - \text{value})$. <i>Default: 0.0</i>
<code>-late_irdrop_data files_or_directories</code>	Specifies the IR drop files or directories to apply when calculating the late arrival times at a single delay corner.
<code>-late_irdrop_files list_of_files</code>	Specifies the list of IR drop files to apply when calculating late arrival times at a single power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. Note: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
<code>-late_temperature_files list_of_files</code>	Specifies the name of the temperature file for temperature aware delay calculation for late corner.
<code>-late_rc_corner rcCornerObj</code>	Specifies the RC corner object to associate with the late corner object.
<code>-late_timing_condition conditional_pairs</code>	Specifies pair list of domains/supply sets and timing conditions to associate with this delay corner object. Note: The <code>-early_timing_condition</code> and <code>-late_timing_condition</code> parameters should be specified together.

<code>-name delayCornerName</code>	Specifies the delay calculation corner to which to add the power domain definition, or to which to update the delay corner or power domain attribute values.
<code>-pg_net_voltages voltage_pairs</code>	Specifies the power/ground net voltages to be used for both early/late timing analysis.
<code>-rc_corner rcCornerObj</code>	Specifies the new RC corner object to associate with this delay corner.
<code>-si_enabled {true false}</code>	Controls signal integrity (SI) analysis. When set to <code>true</code>, the analysis of all MMMC views will include SI analysis by default. You can use this parameter to further determine which analysis views receive SI analysis and which do not. When this parameter is set to <code>false</code> on a delay corner, the software will disable SI analysis for all the views that reference that corner. By default (or when this parameter is set to <code>true</code>), SI analysis is computed for all the views related to that corner - whenever SI is globally enabled. (The global control of SI analysis is determined by the <code>delaycal_enable_si true</code> attribute setting.)
<code>-temperature_files list_of_files</code>	Specifies the name of the temperature file for temperature aware delay calculation for single corner.

`-timing_condition conditional_pairs`

Specifies pair list of domains/supply sets and timing conditions to associate with the defined delay corner object.

Some of the conditional pairs are explained below:

- `timing_condition`: Specifies the default timing condition which applies to all cells not covered by any other timing condition.
- `power_domain_list@timing_condition`: The named timing condition applies to the list of all power domains (defined in a power intent file).
- `supply_set_list@timing_condition`: The named timing condition applies to all blocks tied to the specified supply set.
- `hinst@timing_condition`: The named timing condition applies to the specified hierarchical instance.

The timing conditions must be defined with the `create_timing_condition` command.

Examples

- The following example specifies a list of conditional pairs that are domains/supply sets and the timing conditions associated with the specified delay corner object:

```
update_delay_corner -name ccworst_setup\  
-timing_condition {tc_1 PD1@tc_2 PD2@tc_2 PD3@tc_2 PD4@tc_2}
```

Related Commands

- `create_delay_corner`
- `create_rc_corner`
- `create_timing_condition`

update_io_latency

```
update_io_latency  
[-help]  
[-adjust_source_latency]  
-verbose
```

Provides an automated means of balancing IO and Core clock latencies after the clock network has been added to the design so that pre and post clock tree skew between the clocks is maintained as closely as possible. This results in minimum change of inbound and outbound IO slacks.

This command performs the following actions:

- Measures and calculates ideal average latency for each Core clock.
- Calculates preCTS skew between IO and Core clocks.
- Asserts `set_propagated_clock` on all clock root pins or ports to put clock trees in propagated mode.
- Measures and calculates propagated mode average latency for each Core clock.
- Adjusts `set_clock_latency` on IO clocks network latency to minimize pre to post CTS IO-to-Core clock skew.

In case a single IO clock interacts with multiple Core clocks, the IO clock will be adjusted by the overall average latency of all the related Core clocks combined.

To be effective, this command should only be used after clock trees have been implemented and before the `set_propagated_clock` command is issued. This allows the command to see both the ideal and propagated state of the clock trees.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-adjust_source_latency</code>	Adjusts the source latency of core clock.
<code>-verbose</code>	Provides additional information to the console as adjustments are made to each IO clock.

Related Commands

- `set_propagated_clock`

update_library_set

```
update_library_set  
[-help]  
[-aocv string]  
[-library_side_file string]  
-name libSetName  
[-si string]  
[-socv string]  
[-timing string]
```

Updates an existing specified library set.

Note: You can edit a library set before (or after) the multi-mode multi-corner view definition file is loaded into the design. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode resets the timing, delay calculation, and RC data.

Parameters

-help	Prints out the command usage.
-aocv <i>string</i>	Specifies a list of new AOCV libraries to include in the specified library set.
- library_side_file <i>string</i>	Specifies the library side file.
-name <i>libSetName</i>	Specifies the name of an existing library set to be updated. The library set must have been defined using the <code>create_library_set</code> command.
-si <i>string</i>	Specifies a list of new libraries and user-defined noise (UDN) models to include in the library set.
-socv <i>string</i>	Specifies a list of new SOCV libraries to be included in the library set.
-timing <i>string</i>	Specifies a list of new timing libraries to include in the specified library set. Note: The ECSM and CCS libraries can be very large and loading them may take significant time. You can convert the ASCII NLDM (Liberty .lib), ECSM, and CCS libraries to a binary version using the <code>write_ldb</code> command. For conversion of libraries to a binary version, refer to write_ldb. Instead of the original ASCII libraries, you can specify the following binary libraries in the configuration file: <pre>create_library_set -name libName -timing "AAA.lib BBB.ecsm CCC.ccs"</pre>

Examples

- The following command creates a library set that associates timing libraries with a nominal voltage of 1 volt with the library name IsCOM-1V:

```
tempus> create_library_set -name IsCOM-1V -timing [list stdcell_F_1V.lib ram_F.lib  
pad.lib]
```

The following command changes the timing libraries associated with the library set IsCOM-1V:

```
tempus> update_library_set -name IsCOM-1V -timing [list stdcell_CVF_1V.lib ram_CVF.lib  
pad.lib]
```

Related Commands

- `create_library_set`

update_model_context

```
update_model_context  
[-help]  
-dir string  
[-instances string]
```

Allows the software to read in the context-only boundary models and perform timing analysis without the need to setup a new STA run with a different boundary model.

Parameters

-help	Prints out the command usage.
-dir <i>string</i>	Specifies the directory for the model context.
-instances <i>string</i>	Specifies the instances for context update.

Examples

- The following example shows that commands that are used to update the timing context of a boundary model:

```
read_boundary_model -dir dir_derate_nominal  
...  
set_timing_derate -early 1  
set_timing_derate -late 1  
update_timing  
update_model_context -dir dir_derate_extreme  
set_timing_derate -early 0.8  
set_timing_derate -late 1.2  
update_timing
```

Related Commands

- `write_model_context`
- `create_boundary_model`
- `read_boundary_model`

update_opcond

```
update_opcond  
[-help]  
-name opcondName  
[-process processValue]  
[-temperature temperatureValue]  
[-voltage voltageValue]
```

Updates a set of virtual operating conditions in the specified library that were created using the [create_opcond](#) command.

Parameters

-help	Prints out the command usage.
-name <i>opcondName</i>	Specifies the name of the operating condition to be updated.
-process <i>processValue</i>	Specifies the process value for the operating condition.
-temperature <i>temperatureValue</i>	Specifies the temperature value for the operating condition.
-voltage <i>voltageValue</i>	Specifies the voltage value for the operating condition.

Related Commands

- [set_opcond](#)
- [create_opcond](#)

update_rc_corner

```
update_rc_corner  
[-help]  
[-temperature temperatureValue]  
[-cap_table newcapTableFile]  
-name existingRcCornerName  
[-post_route_res {resFactor1 resFactor2 resFactor3}]  
[-post_route_cap {capFactor1 capFactor2 capFactor3}]  
[-post_route_cross_cap {xcapFactor1 xcapFactor2 xcapFactor3}]  
[-post_route_clock_res {resFactor1 resFactor2 resFactor3}]  
[-post_route_clock_cap {capFactor1 capFactor2 capFactor3}]  
[-pre_route_clock_res resFactor]  
[-pre_route_clock_cap capFactor]  
[-pre_route_res resFactor]  
[-pre_route_cap capFactor]  
[-qrc_tech newFileName]  
[-via_variation_file <string>]
```

Adds or changes attribute values for the specified existing RC corner object.

 You can edit an RC corner object before the multi-mode multi-corner definition file is loaded into the design, or after. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode results in the timing, delay calculation, and RC data being reset.

You can set different postroute scale factors for the postroute engine variants by specifying them as duplets and triplets. For example,

```
resFactor1 resFactor2 resFactor3
```

Where:

- Single value: If you specify one value, the scale factor applies to effort level `low`. Scale factor value of 1 is used for `medium` and `high` by default.
- Duplet: If you specify two values, the first value is used for effort level `low` and the second value is used for `medium`. Scale factor value of 1 is used for `high` by default.
- Triplet: If you specify three values, the first value is used for effort level `low`, the second value is used for `medium`, and the third value is used for `high`.

Note: If the `read_spef` command is specified without the `-rc_scale` parameter, for example, "`read_spef -rc_corner early_spef_${rc_corner}`", then the software does not apply capacitance scale factor specified in `-post_route_cap` and `-post_route_cross_cap` parameters. If the `read_spef` command is specified with the `-rc_scale` parameter, for example, "`read_spef -rc_corner early_spef_${rc_corner}`", then the software applies the scale factor.

`-rc_scale "`, then the software applies the capacitance scale factor. Here, no factor is specified in the `-rc_scale` option.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-cap_table newCapTableFile</code>	Specifies a new capacitance table to use for extraction when using this RC corner.
<code>-pre_route_cap capFactor</code>	Specifies the capacitance scale factor for RC Extraction in pre-route mode.
<code>-pre_route_clock_cap capFactor</code>	Specifies the scale factor for capacitance of clock nets in preroute mode. Default: 0 When this parameter is not specified, the value specified with the <code>-pre_route_cap</code> parameter is used for preroute extraction. When specified, this parameter overrides the value specified with the <code>-pre_route_cap</code> parameter for clock nets.
<code>-pre_route_clock_res resFactor</code>	Specifies the scale factor for resistance of clock nets in preroute mode. Default: 0 When this parameter is not specified, the value specified with the <code>-pre_route_res</code> parameter is used for preroute extraction. When specified, this parameter overrides the value specified with the <code>-pre_route_cap</code> parameter for clock nets.
<code>-pre_route_res resFactor</code>	Specifies the resistance scale factor for RC Extraction in pre-route mode.
<code>-post_route_cap {capFactor1 capFactor2 capFactor3}</code>	Specifies the capacitance scale factor for RC Extraction in post-route mode.

<pre>-post_route_clock_cap {capFactor1 capFactor2 capFactor3}</pre>	Specifies the scale factor for capacitance of clock nets in the postroute extraction mode. Default: 0 When this parameter is not specified, the value specified with the <code>-post_route_cap</code> parameter is used for postroute extraction. When specified, this parameter overrides the value specified with the <code>-post_route_cap</code> parameter.
<pre>-post_route_clock_res {resFactor1 resFactor2 resFactor3}</pre>	Specifies the scale factor for resistance of clock nets in the postroute extraction mode. Default: 0 When this parameter is not specified, the value specified with the <code>-post_route_res</code> parameter is used for postroute extraction. When specified, this parameter overrides the value specified with the <code>-post_route_res</code> parameter for clock nets.
<pre>-post_route_res {resFactor1 resFactor2 resFactor3}</pre>	Specifies the resistance scale factor for RC extraction in post-route mode.
<pre>-name existingRcCornerName</pre>	Specifies the name of the existing RC corner object to update.
<pre>-qrc_tech newFileName</pre>	Specifies a new QRC technology (<code>.tch</code>) file which is used to perform sign-off RC extraction.
<pre>-temperature newTempValue</pre>	Specifies a new temperature, in units of Celsius, to use to derate resistance values.
<pre>-post_route_cross_cap {xcapFactor1 xcapFactor2 xcapFactor3}</pre>	Specifies the cross-coupling capacitance scale factor for RC extraction in postroute mode.

`-via_variation_file string`

Specifies a file for modeling via variation. The VIA variation file lists up all the VIA layer names with the corresponding multiplier. Each RC corner can have its own VIA variation file.

For example:

```
update_rc_corner
-name rcCornerName1 \
-via_variation_file viaVariationFileName1
update_rc_corner
-name rcCornerName2 \
-via_variation_file viaVariationFileName2
```

Examples

- The following command creates an RC corner called `rc-cbest` that uses the capacitance table `myTech_bc.CapTbl`, and derates the resistance values based on the temperature of 50 Celsius:
`create_rc_corner -name rc-cbest -cap_table myTech.4_bc.CapTbl -temperature 50`
- The following command changes the capacitance table used by RC corner `rc-cbest` to `myCap.2_bc.capTbl`, and the temperature by which resistance values are derated to 25 Celsius:
`update_rc_corner -name rc-cbest -cap_table myCap.2_bc.capTbl -temperature 25`

Related Commands

- `create_rc_corner`

update_timing

```
update_timing
[-help]
[-full]
```

Updates timing for the current design.

Parameters

-help	Prints out the command usage.
-full	Runs a full timing update for the current design overriding the default behavior of running incremental timing updates, where only a minimal amount of computation is necessary to update the timing analysis information. Note that for full SI accuracy during reporting, an explicit <code>update_timing -full</code> command is required after incrementally applying constraints such as, <code>set_timing_derate</code>, <code>set_input_delay</code>, <code>set_max_delay</code>, <code>set_clock_groups</code>, or <code>create_clock</code> (these constraints only affect SI delay calculation). Note: It is not required to run the <code>update_timing</code> command without the <code>-full</code> parameter because timing is automatically updated by the <code>report_timing</code> and <code>report_constraint</code> commands - except after incrementally applying constraints that only affect SI delay calculation.

Related Commands

- `check_timing`
- `report_timing`
- `report_constraint`

update_timing_condition

```
update_timing_condition  
[-help]  
[-library_sets string]  
-name timingConditionName  
[-opcond string]  
[-opcond_library string]
```

Updates the virtual operating conditions (set using [create_timing_condition](#) command) with the new settings.

Parameters

-help	Prints out the command usage
-library_sets <i>string</i>	Specifies list of library sets to associate with the specified timing condition.
-name <i>timingConditionName</i>	Specifies a unique name for the timing condition. This name must exist or an error is issued.
-opcond <i>string</i>	Specifies a single name of an operating condition to associate with the timing condition.
-opcond_library <i>string</i>	Specifies a name of the library to search for the defined operating condition.

Examples

- The following example shows the `update_timing_condition` command performs an update on the specified timing condition:

```
create_timing_condition -name TC1 -library_sets {ls1 ls2} -opcond oc1  
update_timing_condition -name TC1 -library_sets {ls3}; # TC1 now only has libset ls3
```

- The following commands result in identical results. However, the first command creates the bin TC2 and the second command updates both the options:

```
create_timing_condition -name TC2 -library_sets {ls1 ls2} -opcond oc1  
update_timing_condition -name TC2 -library_sets {ls1 ls2} -opcond oc1
```

Related Commands

- `create_timing_condition`

write_boundary_model

```
write_boundary_model  
[-help]  
-dir string  
-output_dir string  
[-overwrite]
```

Allows you to export files - Verilog, SPEF, TWF, and SDC - from a boundary model.

This command cannot be run when there is an active design in the session. So the expected usage is to start a Tempus session, and then immediately run one or more export commands, such as:

```
write_boundary_model -dir HCELL1_model -output_dir HCELL1_export -overwrite  
write_boundary_model -dir HCELL2_model -output_dir HCELL2_export -overwrite
```

After the export is complete, the session is still usable for other commands.

Parameters

-help	Prints out the command usage.
-dir <i>string</i>	Specifies the boundary model directory.
-output_dir <i>string</i>	Specifies the target directory for exported boundary model files.
-overwrite	Allows you to overwrite the existing target directory.

write_global_slack_report

```
write_global_slack_report  
[-help]  
[-early]  
[-late]  
[-rise]  
[-fall]  
[-include_ports]  
[-max_slack val]  
[-min_slack val]  
[-view view_name]  
[> | >> file_name]  
[pin_port_list]
```

Reports early and late slacks on every instance pin in the design.

This command computes and reports the required time and slack values of the specified pins.

Parameters

<code>-help</code>	Prints out the command usage.
<code>> >> filename</code>	Specifies the output file name. When specified with <code>></code>, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with <code>>></code>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. Note: To write a compressed report, add the <code>.gz</code> extension to the file name.
<code>-early/-late</code>	Specifies the mode for which slack is to be reported.
<code>-fall/-rise</code>	Specifies the transition for which slack is to be reported.
<code>-include_ports</code>	Reports slack information for ports. By default, the slack information is reported for pins only.
<code>-max_slack val</code>	Reports pins that have upper bound slack values less than the specified value.
<code>-min_slack val</code>	Reports pins that have lower bound slack values less than the specified value. Note: This parameter is obsolete and will be removed in a future release. Cadence recommends that you use the <code>-max_slack</code> parameter.
<code>pin_port_list</code>	Specifies the list of pins or ports for which slack information is to be reported.
<code>-view view_name</code>	Reports slack information for the specified view.

Examples

- The following command reports the early and late slacks on every instance pin in the design:

```
tempus > write_global_slack_report > out.rpt

# Unit: 1ns
# <late_rise> <late_fall> <early_rise> <early_fall> <view_name> <hpin_name>
# -----
*          *          *          *          (null)      u2/Q
*          *          *          *          (null)      u8/Q
*          *          *          *          (null)      b11/A
*          *          *          *          (null)      b11/Y
0.823      0.347      0.115      0.501      (null)      u10999/A
0.823      0.347      0.115      0.501      (null)      u10999/Y
# -----
```

- The following command reports slack for a pin collection:

```
tempus> set x [get_pins -hier */A]

0x14 <---- 'x' stores Pointer for pin collection
```

- The following command will generate a global slack report for pin collection as defined in "x":

```
tempus> write_global_slack_report $x

# Unit: 1ns
# <late_rise> <late_fall> <early_rise> <early_fall> <view_name> <hpin_name>
# -----

write_ipd_scope

```
write_ipd_scope  
[-help]  
[-context_only]  
[-exclude <string>]  
[-include <string>]  
[-scope_data <string>]  
[[[-bounded_corners ] [-include_derates ] [-include_constraints ] [-overwrite ] [<dir_name>]]  
| [[[-early_structural_checks <string>] [-out_file_prefix <string>] [-  
power_domain_count_threshold <integer>]] | [-write_all_paths <string>]]
```

Writes out the IPD scope in the scope creation run. The scope is generated in the directory location specified as the command argument.

This command is used to write out the IPD Scope in the scope creation run. The scope is generated in the directory location specified as command argument - that provides options to control whether constraints and derates are to be written out in the scope or not.

Parameters

-help	Prints out the command usage.
-context_only	Re-generates constants that will be a part of context data.
-early_structural_checks <string>	Specifies the early check types to be performed. The valid values are: • clock_divergence • multiple_pd_data_paths • multiple_pd_clock_paths • multiple_pd_paths
-exclude <string>	Specifies the netlist exclusions. The supported options are clock, port, async, scanchain, and <\$list_of_PD_combinations>.

<code>-include <string></code>	Specifies the netlist filter inclusions - the supported options are: • <code>equivalent_power_domains</code> • <code>internal_power_domains</code> • <code>timing_disabled_network</code> • <code>equivalent_supply_voltage</code>
<code>-include_constraints</code>	Allows IPD scope to be written with victim constraints.
<code>-include_derates</code>	Allows IPD scope to be written with timing derates.
<code><dir_name></code>	Specifies the output directory containing partial Verilog and partial SPEF, or marking data, and context data.
<code>-bounded_corners</code>	Generates a bounded corner scope based on the minimum/maximum voltage combination analyzed in the scope creation run. By default, the software writes out the maximum voltage combination details in the scope, if this parameter is not specified in the bounded corner run.
<code>-scope_data <string></code>	Specifies the scope data to be written from minimum or maximum voltage combination.
<code>-out_file_prefix <string></code>	Specifies the outfile for structural checks.
<code>-overwrite</code>	Overwrites the already present directory's content with the new content.
<code>- power_domain_count_threshold <integer></code>	Specifies the threshold for the power domain count reported using the <code>multiple_pd_paths</code> option.
<code>-write_all_paths <string></code>	Writes all the IPD paths and uses the name of the path descriptions' file.

Examples

- The following command generates a bounded corner scope based on the minimum/maximum voltage combination analyzed in the scope creation run:

```
tempus > write_ipd_scope -bounded_corner -overwrite bounded_corner_scope
```

This command writes out the derates and constraints in the IPD scope, and overwrites an existing scope generated with same directory name argument.

write_ldb

```
write_ldb  
[-help]  
ldb_file  
-library string
```

Converts text library to Cadence binary format library called LDB.

You can use LDB to run Tempus analysis. The ECSM and CCS libraries can be very large and loading them may take significant time. You can convert the ASCII NLDM (Liberty .lib), ECSM, and CCS libraries to LDB by using the `write_ldb` command.

When loading the design, the timing libraries will be read faster because the software reads the binary versions.

Instead of the original ASCII libraries, you can specify LDB in the `read_libs` command or `create_library_set` command in MMMC configuration file.

Notes:

- Tempus generated LDB files can be used in Tempus, Innovus, Voltus, Genus, and Conformal software.
- The LDB files are not forward compatible, that is, the LDB generated in one version cannot be used with the prior versions of the software.
- The software does not support concatenated Liberty library (multiple libraries in the same dotlib file) files during LDB conversion. To use these files, you are required to separate out individual libraries before converting to individual LDB files.

Parameters

<code>-help</code>	Prints out the command usage.
<code>ldb_file</code>	Specifies the name of the generated compiled library file.
<code>-library string</code>	Specifies the name of the input library file.

Examples

- The following example illustrates the conversion of libraries to LDB:

```
write_ldb -library A.lib A.ldb
```

Related Commands

- `check_ldb_version`

write_loop_break_sdc

```
write_loop_break_sdc  
[-help]  
out_file  
-in_file string
```

Generates SDC file containing constraints for combinational loop breaking. The command selects the disable arc (s) with flag set to 1 from the third-party report file, and generates the equivalent SDC commands in an output file.

You can load the output SDC file at any time during an Tempus session. To load the file, use the [read_sdc](#) command.

Parameters

-help	Prints out the command usage.
out_file	Specifies the name of the output SDC file.
-in_file string	Specifies the disabled time arcs report that you generate using third-party tool.

Command Order

Use this command after generating the disable arcs report.

Examples

The following command generates an `etsCombLoopBreak.sdc` file when the input is a `disable_arcs.rpt` file:

```
tempus > write_loop_break_sdc -in_file disable_arcs.rpt -out_file etsCombLoopBreak.sdc
```

The contents of `disable_arcs.rpt` file are as follows:

Cell or Port	From	To	Sense	Flag Reason

:				
uchip_core/u_s5_power	oLpcSd_4_	orig_oSmAcpiSd_4_	*	1
:				

The contents of output file `etsCombLoopBreak.sdc` are as follows:

```
:  
set_disable_timing -from {oLpcSd_4_} -to {orig_oSmAcpiSd_4_}  
[get_cells {uchip_core/u_s5_power}]  
:
```

write_model_context

```
write_model_context  
[-help]  
-dir string  
[-overwrite]  
-reference_dir string
```

Allows the software to create a single complete boundary model and a timing context-only boundary model, when several boundary models for a block need to be created with different timing settings (such as, derates, timing global variables).

The timing context-only boundary models do not have any netlist or parasitic information and provide only timing context data to perform timing analysis using the boundary models. Thus, these can be created with a much smaller run time using the `write_model_context` command.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-dir <i>string</i></code>	Specifies the directory for the model context.
<code>-overwrite</code>	Allows the software to overwrite the existing directory.
<code>-reference_dir <i>string</i></code>	Specifies the directory path of the original model.

Examples

- The following example shows the commands that are used to create two boundary models. The first boundary model `dir_derate_nominal` is created using the `create_boundary_model` command and is a complete boundary model.

```
set_timing_derate -early 1
set_timing_derate -late 1
update_timing
create_boundary_model -dir dir_derate_nominal -overwrite
```

The second boundary model `dir_derate_extrem` is a context-only boundary model that is created using the `write_model_context` command. This model provides the timing context for the `dir_derate_nominal` boundary model:

```
set_timing_derate -early 0.8
set_timing_derate -late 1.2
update_timing
write_model_context -dir dir_derate_extreme -overwrite -reference_dir dir_derate_nominal
```

- The following example shows the commands that are used to read the complete boundary model. The context can be updated using the `update_model_context` command to update the timing context of the boundary model:

```
read_boundary_model -dir dir_derate_nominal
...
set_timing_derate -early 1
set_timing_derate -late 1
update_timing
update_model_context -dir dir_derate_extreme
set_timing_derate -early 0.8
set_timing_derate -late 1.2
update_timing
```

- [create_boundary_model](#)
- [read_boundary_model](#)

write_path_descriptions

```
write_path_descriptions  
[-help]  
var_name  
-out_file string
```

Writes out the path descriptions of all the timing paths specified in the variable (path collection) to an ASCII file.

The output file contains a set of [report_timing](#) commands for each timing path in the given path collection. The file also includes a complete description of each timing path captured through timing points along with the clock and edge information.

The path description of a given collection of paths can be read back and the same path configuration can be recreated in another Tempus session. This allows to process and compare the timing, attributes, and other characteristics of the specified paths.

Parameters

-help	Prints out the command usage.
var_name	Specifies the object collection of timing paths. The input must be a single collection. If you need to write out path descriptions of collections generated with different analysis types or path collections, a single collection can be created by appending all the collections using the append_to_collection command.
- out_file string	Redirects output to the specified file.

Examples

- The following command writes out descriptions of late GBA paths - when the `-path_type` parameter is not specified:

```
set path_coll [report_timing -collection]  
write_path_descriptions $path_coll > PathSpecFile.txt
```

The output file PathSpecFile.txt contains:

```
report_timing -net -path_type full_clock -late -from_rise A -through_rise B -  
through_rise C \
```

```
-to_rise D -view slow_v -clock_from clk1 -edge_from lead -clock_to clk2 -edge_to lead
```

- The following command writes out descriptions of late PBA paths when the `-path_type full` option is specified:

```
set path_coll [report_timing -collection -retime path_slew_propagation -path_type full]

write_path_descriptions $path_coll > PathSpecFile.txt
```

The output file `PathSpecFile.txt` contains:

```
report_timing -net -path_type full_clock -late -from_rise A -through_rise B -
through_rise C \
    -to_rise D -view slow_v -clock_from clk1 -edge_from lead -clock_to clk2 -edge_to lead
```

Note: The output does not show retime details. You should use the `read_path_descriptions -retime` parameter to analyze retime collections that are defined with the `write_path_descriptions` command.

- The following command writes out descriptions of both the early and late GBA paths:

```
set path_coll [report_timing -collection]
set path_coll_early [report_timing -collection -early]
append_to_collection path_coll $path_coll_early
write_path_descriptions $path_coll > PathSpecFile.txt
```

The output file `PathSpecFile.txt` contains:

```
report_timing -net -path_type full_clock -late -from_rise A -through_rise B -
through_rise C \
    -to_rise D -view slow_v -clock_from clk1 -edge_from lead -clock_to clk2 -edge_to lead
report_timing -net -path_type full_clock -early -from_rise A through_rise B -to_rise D -
view \
    slow_v -clock_from clk1 -edge_from lead -clock_to clk2 -edge_to lead
```

write_sdc

```
write_sdc  
[-help]  
[-clocks <string>]  
[-commands <string>]  
[file_name]  
[-exclude_annotated <string>]  
[-path_adjust_only]  
[-path_group_only]  
[-pins <string>]  
[-strict_sdc]  
[-view <string>]  
[-vt_skew_derate_only]
```

Generates the timing constraints file in a third-party compiler format.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-clocks <string></code>	Specifies the name of the clocks to be included in the SDC file.
<code>-commands <string></code>	Specifies the name of the commands to be included in the SDC file.
<code>file_name</code>	Specifies the name of the constraints file. By default, the constraint file is generated in the current directory. To save to a different directory, you need to specify the complete path.
<code>-exclude_annotated string</code>	Generates the constraints file excluding annotated constraints. You can specify one of the following options: • <code>delays</code> • <code>checks</code> • <code>transitions</code>
<code>-path_adjust_only</code>	Exports <code>set_path_adjust_group</code> and <code>set_path_adjust</code> constraints.
<code>-path_group_only</code>	Exports <code>group_path</code> constraints.
<code>-pins <string></code>	Specifies the name of the pins to be included in the SDC file.
<code>-strict_sdc</code>	Produces a SDC file where functions to manipulate collections are expanded. For example, the <code>remove_from_collection</code> <code>all_inputs</code> , <code>all_outputs</code> , <code>all_clocks</code> , and <code>filter</code> commands are replaced by the resulting list of objects. Note: When you specify the <code>-strict_sdc</code> parameter, a warning is issued stating that using the parameter produces a constraint file containing SDC standard constraints only. This may cause some design constraints to be dropped.
<code>-view viewName</code>	Specifies a view name to obtain the desired SDC.
<code>-vt_skew_derate_only</code>	When specified, the software will check the voltage threshold (VT) skew configuration, and report the VT skew derate details as per the voltage groups defined.

Command Order

Use this command after reading in a timing constraints file.

Examples

- The following command generates constraints file `newc` and saves the generated file in the directory `new`:

```
tempus > write_sdc new/newc
```

- Specifying the following constraints will have new entries in the output constraints file:

```
tempus > set_annotated_delay -from u1/A -to u1/Y -cell 2
tempus > set_annotated_check 2 -setup -from f0/CK -to f0/D
```

The `write_sdc` output will be as follows:

```
set_annotated_delay -cell 2 -from [get_pins {u1/A}] -to [get_pins {u1/Y}]
set_annotated_check -setup -from [get_pins {f0/CK}] -to [get_pins {f0/D}] 2
```

- For the following constraints in the design :

```
tempus > set_annotated_delay -from u1/A -to u1/Y -cell 2
tempus > set_annotated_transition 2 u1/A
tempus > set_annotated_check 2 -setup -from f0/CK -to f0/D
```

The `write_sdc -exclude_annotated delays` output will be as follows:

```
set_annotated_transition 2 [get_pins {u1/A}]
set_annotated_check -setup -from [get_pins {f0/CK}] -to [get_pins {f0/D}] 2
```

The `write_sdc -exclude_annotated {delays transitions}` command outputs the following:

```
set_annotated_check -setup -from [get_pins {f0/CK}] to [get_pins {f0/D}] 2
```

Writes delays to a Standard Delay Format (SDF) file. The `write_sdf` command can generate both plain-text and GNU zipped (.gz) SDF files.

By default, the `write_sdf` command uses the delays already cached by the system and writes only values of the triplets.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-gate_level_sim_model</code>	Writes out the gate-level simulation (GLS) SDF file.
<code>--adjust_setuphold_for_zero_hold_slack</code>	Adjusts the hold timing check to meet non-negative slack values.
<code>-base_delay</code>	Writes out base delay information in the SDF file.
<code>-cell_timing</code> { <i>all</i> <i>none</i> <i>nochecks</i> }	Specifies which cell delays and timing checks to write out. <i>Default:</i> <i>all</i> <i>all</i> - Writes all cell delays and timing checks to the SDF file. This is the default. <i>nochecks</i> - Disables the writing of timing checks only. <i>none</i> - Prevents cell delays and timing checks from being written into the SDF file.

<code>-collapse_internal_pins</code>	Collapses arcs across internal pins to a single primary input to primary output arc. Use the <code>-collapse_internal_pins</code> parameter when the SDF file being generated is intended for use by an application that does not support the same internal pin structure in its leaf cell libraries (for example, Cadence VXL and NCsim Verilog simulation products). Do <i>not</i> use this parameter to generate an SDF file intended for use within the Tempus flow, or by third party tools that utilize the same Liberty timing models. <i>Default:</i> Arcs between internal pins in a timing model are written to the SDF file as explicit annotations to and from the internal pins internal pins.  For example, assume the following arc between internal pins: The following SDF would be generated by default: <pre>(U1/in1 U1/IntPinA (1::1) (1::1)) (U1/IntPinA U1/IntPinB (2::2) (2::2)) (U1/IntPinB U1/out1 (3::3) (3::3))</pre> If you specify <code>-collapse_internal_pins</code>, the resulting SDF would show a single arc with the merged delays: <pre>(U1/in1 U1/out1 (6::6) (6::6))</pre>
<code>-infer_condelse</code>	Writes <code>CONDElse</code> constructs with the default value when a <code>COND</code> construct is written. Note: Use this argument with the <code>-version 3.0</code> option.

<code>-delimiter char</code>	Specifies the hierarchy divider character to use in the output file. This option sets the hierarchy divider of only the <code>write_sdf</code> command. If omitted, the default hierarchy divider character (/) is used as the <code>write_sdf</code> default.
<code>-delta_delay</code>	Writes out delta delay values to the SDF file.
<code>-edges {edged library noedge check_edge}</code>	Specifies the edges values. • <code>check_edge</code> - Keeps edge specifiers on timing check arcs but does not add edge specifiers on delay arcs. • <code>edged</code> - Keeps edge specifiers on timing check arcs and delay arcs. • <code>library</code> - Assumes that the <code>sdf_edges</code> attributes are specified in the <code>.lib</code> file. The default <code>sdf_edges</code> value of a timing arc is <code>noedge</code>. • <code>noedge</code> - Does not keep edge specifiers. <i>Default:</i> <code>edged</code> Refer to Table for full qualifications of the possible values for the edges option.
<code>-exclude_cells</code>	Specifies a list of leaf-cell or hierarchical instances whose timing data will be excluded from the the SDF (Standard Delay Format) file. If you specify a hierarchical instance, the timing data for all leaf-cells below the level of hierarchy will be omitted from the SDF file.
<code>-exclude_cells_keep_io_nets</code>	Restricts the filtering to just the annotations which are completely enclosed by the cell. Annotations to or from the cell will be preserved. By default, when the <code>-exclude_cells</code> parameter is used, any annotations within the excluded cell and any annotations to or from the excluded cell are filtered from the SDF.

<code>-exclude_cells_keep_top_level_nets</code>	Allows you to configure the handling of top-level interconnect annotations to an instance that is excluded from the SDF using the <code>write_sdf -exclude_cells</code> parameter. When this parameter is specified, the interconnect arcs which span to the ports of the instance will be included in the SDF. By default, no interconnect arcs to the instance are included. The delay annotated will be the worst-case delays of the top-level nets to/from the first level sink/source pins within the block that traverse a given input/output port of the instance, respectively.
<code>-exclude_disabled_arcs</code>	Excludes user set disabled arcs in the Standard Delay Format (SDF) file. If the user sets this option, the disabled arcs set by commands <code>set_mode</code>, <code>set_disable_timing</code>, and <code>set_case_analysis</code> are excluded.
<code>-exclude_disabled_modes</code>	Excludes timing arcs that have been disabled due to an active library mode set by the <code>set_mode</code> command, from appearing in the SDF file.
<code>-exclude_whatif_arcs</code>	Excludes what-if arcs in the SDF file.
<code>sdf_file</code>	Specifies the name of the SDF output file.
<code>-zero_negative_delays</code>	Converts all negative interconnect and <code>IOPATH</code> delays to zero.
<code>-ideal_clock_network</code>	Marks delays of delay arcs, that are on the ideal clock networks, as 0 in the SDF file.
<code>-include_cells string</code>	Specifies a list of leaf-cell or hierarchical instances to be only included in the SDF file.
<code>-include_variation</code>	When the selected analysis type is SOCV, the <code>-include_variation</code> parameter can be used to export SDF delays and check values, including the variation component. By default, the SDF delays and check values will not have the mean + N*sigma value.
<code>-infer_condelse</code>	Writes CONDELSE constructs with the default value when a COND construct is written.

<pre>-interconnect {all none noport noinput nooutput}</pre>	Specifies which interconnect delays to write. • all - Writes all <code>INTERCONN</code> delays into the SDF file. This is the default if the <code>-interconnect</code> option is not specified. • none - No <code>INTERCONN</code> delays are written into the SDF file. • noport - No top level port <code>INTERCONN</code> delays are written into the SDF file. • nooutput - Disables only the output port <code>INTERCONN</code> delays. <i>Default:</i> <code>all</code>
<pre>-map_file {file1 file2 ...}</pre>	Specifies a list of map files. The map files can be used to determine what is written into the SDF files. For example, a map file can provide delay information on internal pins which are not defined in the timing library. Syntax for a map file (for a cell) is as follows: • A template section (the text to output) that reference variables of the form <code>\$<number></code> • A variable definition section that tells the expression to evaluate to obtain the value

```
-recrem [merge_always | split |  
merge_when_paired]
```

Determines how RECOVERY and REMOVAL timing checks are written.

- `merge_always` - Always writes combined RECREM checks, even if either a RECOVERY, or a REMOVAL, check does not exist.
For example, if a RECOVERY check exists, but a REMOVAL check does not, the software writes a combined RECREM check in the SDF file as follows:

```
RECREM ( value ) ( value ) ( ) ( )
```

- `split` - Splits the RECREM checks into a RECOVERY check and a REMOVAL check.
- `merge_when_paired` - Writes combined RECREM checks only when both a RECOVERY and a REMOVAL check exist.
For example, if both a RECOVERY and a REMOVAL check exist, the software writes a combined RECREM check in the SDF file as follows:

```
RECREM ( value ) ( value ) ( value ) ( value )
```

However, if a RECOVERY check exists, but a REMOVAL check does not, the software only writes the RECOVERY check in the SDF file:

```
RECOVERY ( value ) ( value )
```

Default: `merge_always`

Note: The RECREM sum should be zero or greater than zero. A negative value will be adjusted to enforce this condition. This is an SDF v3.0 requirement (the software may issue a warning).

<code>-map_removal_to_hold</code>	Converts the SDF v2.1 unsupported <code>REMOVAL</code> (and the <code>REMOVAL</code> portion of the <code>RECREM</code> constructs) to <code>HOLD</code> checks when used with the <code>-version 2.1</code> option. <i>Default:</i> Not to write out the unsupported checks. Converts the <code>REMOVAL</code> checks to <code>HOLD</code> checks when combined with the <code>-version 3.0</code> option. The <code>RECREM</code> checks are split into a <code>RECOVERY</code> check and a <code>HOLD</code> check. This option automatically splits the <code>RECREM</code> checks. <i>Default:</i> To maintain the version 3.0 checks.
<code>-max_view viewName</code>	Uses the late delay from the specified analysis view to populate the SDF max slot, when in multi-mode multi-corner analysis mode.
<code>-min_clock_si_threshold number</code>	Specifies the absolute minimum delta delay change threshold on the clock path to be written into the SDF file. Time unit is in seconds. <i>Default:</i> 1e-20
<code>-min_data_si_threshold number</code>	Specifies the absolute minimum delta delay change threshold on the data path to be written into the SDF file. Time unit is in seconds. <i>Default:</i> 1e-20

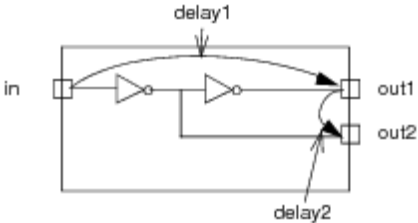

<pre>-min_period_edges {posedge negedge both none}</pre>	Specifies how to write out minimum <code>PERIOD</code> checks. Two check arcs are always created for the <code>min_period</code> check when you read in a <code>.lib</code> file. The following options let you keep or remove the positive edge, the negative edge, both edges, or no edges from the <code>PERIOD</code> statement in the <code>.sdf</code> file. • <code>posedge</code> - Writes out one positive edge <code>PERIOD</code> check. • <code>negedge</code> - Writes out one negative edge <code>PERIOD</code> check. • <code>both</code> - Writes out both the positive edge and the negative edge <code>PERIOD</code> checks. This is the default. • <code>none</code> - Writes out one <code>PERIOD</code> check without any edge specifier.
<pre>-min_view viewName</pre>	Uses the early delay from the specified analysis view to populate the SDF <code>min</code> slot, when in multi-mode multi-corner analysis mode.
<pre>-multi_drive_net_syntax string</pre>	Specifies the multi-drive nets as ports or interconnects. You can use the <code>interconnect</code> and <code>port</code> options if you need to define the net delays of multi-driven nets (clock mesh) as interconnects or ports respectively in the SDF.
<pre>-no_derate</pre>	Writes non-derated delays to the Standard Delay Format (SDF) file. By default, the <code>set_timing_derate</code> command writes scaled delays to the SDF file. When the <code>-no_derate</code> parameter is specified, the <code>write_sdf</code> command removes all the applied derates.
<pre>-no_escape</pre>	Writes out object names without escaping hierarchical dividers. Normally, when writing out a SDF file, the hierarchical divider (<code>/</code>) is escaped because it is a special character.
<pre>-exclude_negative_checks</pre>	Converts all negative timing check values to <code>0.0</code>.
<pre>-path name</pre>	Specifies the sub-block name.

<code>-precision <i>non_neg_integer</i></code>	Controls the number of digits appearing after the decimal point in the output SDF file. The default precision is the value of the <code>report_precision</code>.
<code>-process</code>	Specifies one or a combination of the following process names that will appear in the header of the generated SDF file: • <code>best</code> • <code>typical</code> • <code>worst</code> Use the colon delimiter to specify multiple process names. For example: <pre>-process best:typical:worst</pre> In the above example, the header of the generated SDF file will contain: <pre>(PROCESS "best:typical:worst")</pre>
<code>-recompute_delaycal</code>	Instructs the software to recompute any necessary data required for a complete SDF file before exporting. By default, only the existing data that has been computed for STA is exported to the SDF. You must use this parameter to ensure that the SDF file is complete for general use in other applications.

<code>-recompute_parallel_arcs</code>	Instructs the software to temporarily recompute delays with separate delay calculation for parallel arcs. The software normally operates in a high performance mode which optimizes the handling of multiple timing arcs between input and output pin pairs. By default, the SDF file generated will contain the same delay information for all of these arcs. To have the SDF recalculated with explicit pin pair data, you should use the option <code>-recompute_parallel_arcs</code> to cause delays for each parallel arc to be explicitly calculated. It is recommended to use this option for generating SDF for functional simulation applications. Note: When you use the <code>write_sdf -recompute_parallel_arcs</code> option timing analysis is performed again. You need to obtain a new delay calculation to generate the SDF, and another delay calculation to put the system back to where it was before <code>write_sdf</code> was specified. Since delay calculation is run again, timing analysis will be reset. Note: The <code>-recompute_parallel_arcs</code> parameter is obsolete. This parameter still works in this release, but to ensure compatibility with future releases update your scripts to use the <code>-recompute_delaycal</code> parameter instead.
<code>-scale float</code>	Specifies a multiplier to the delay values used in the SDF file. The delay values are scaled, but the units are the same. <i>Default:</i> 1

<pre>-setuphold [merge_always split merge_when_paired]</pre>	Determines how <code>SETUP</code> and <code>HOLD</code> timing checks are written. • <code>merge_always</code> - Always writes combined <code>SETUPHOLD</code> checks, even if either a <code>SETUP</code> or a <code>HOLD</code>, check does not exist. For example, if a <code>SETUP</code> check exists, but a <code>HOLD</code> check does not, the software writes a combined <code>SETUPHOLD</code> check in the SDF file as follows: <pre>SETUPHOLD (value) (value) () ()</pre> • <code>split</code> - Splits the <code>SETUPHOLD</code> timing checks into separate <code>SETUP</code> and <code>HOLD</code> checks. • <code>merge_when_paired</code> - Writes combined <code>SETUPHOLD</code> checks only when both a <code>SETUP</code> and a <code>HOLD</code> check exist. For example, if both a <code>SETUP</code> and a <code>HOLD</code> check exist, the software writes a combined <code>SETUPHOLD</code> check in the SDF file as follows: <pre>SETUPHOLD (value) (value) (value) (value)</pre> However, if a <code>SETUP</code> check exists, but a <code>HOLD</code> check does not, the software only writes the <code>SETUP</code> check in the SDF file: <pre>SETUP (value) (value)</pre> <i>Default:</i> <code>merge_always</code>
<pre>-split_recrem</pre>	Splits the <code>RECREM</code> checks into a <code>RECOVERY</code> check and a <code>REMOVAL</code> check. <i>Default:</i> To write the combined <code>RECREM</code> check. Note: Use this option only with the <code>version 3.0</code> option.

<pre>-split_setuphold</pre>	Splits the <code>SETUPHOLD</code> timing checks into separate <code>SETUP</code> and <code>HOLD</code> checks. <i>Default:</i> To write the combined <code>SETUPHOLD</code> checks. Note: In SDC v3.0, the negative values are illegal in <code>SETUP</code>, <code>HOLD</code>, <code>RECOVERY</code>, and <code>REMOVAL</code> checks. Therefore, the negative values are converted to zero automatically with the <code>-split_setuphold</code> and <code>-split_recrem</code> parameters.
<pre>-target_application { sta verilog }</pre>	Allows customization of the SDF output for use with STA or Verilog applications. You can select the following options: • sta: You can use the <code>sta</code> option to configure the SDF output for use with static-timing analysis (STA) applications. This includes sign-off timing analysis with products, such as Cadence Tempus, as well as for working with implementation flows that use STA for internal timing analysis. The <code>sta</code> option preserves maximum accuracy and generates SDF output that matches the structure of the Liberty timing libraries. This option is equivalent to the following options: <pre>write_sdf -interconnect all, -cell_timing all, -edges edged, -setuphold merge_when_paired, and -recrem merge_when_paired.</pre> • verilog: You can use the <code>verilog</code> option to generate SDF output that is compatible with Cadence Verilog-XL or Verilog-NC simulators. This option is equivalent to the following options: <pre>write_sdf -zero_negative_delays -edges check_edge, -setuphold merge_when_paired, -recrem merge_when_paired, -min_period_edges -none, -collapse_internal_pins, and -recompute_parallel_arcs.</pre> When the <code>-target_application</code> option is not specified then by default SDF output is configured for use with STA applications.

<code>-gate_level_sim_model</code>	Writes out the GLS SDF file.
<code>-temperature</code>	Defines the temperature values that will appear in the header of the generated SDF file. Use the colon delimiter to specify multiple temperature values. For example: <pre>-temperature -40.0:25.0:125</pre> In the above example, the header of the generated SDF file will contain: <pre>(TEMPERATURE -40.0:25.0:125)</pre>
<code>-transform_out_to_out_arcs</code>	Writes out all output-to-output timing arcs as input-to-output arcs. Input-to-output arc delays are computed by adding the delay from the input pin to one of the output pins plus the delay from that output pin to the other output pin. For instance, in the following figure, the delay between <code>in</code> and <code>out2</code> would be the sum of <code>delay1</code> and <code>delay2</code>. 
<code>-typical_view viewName</code>	Uses the late delay from the specified analysis view to populate the SDF <code>typ</code> slot, when in multi-mode multi-corner analysis mode.
<code>-version {2.1 3.0}</code>	Specifies whether to generate the SDF V2.1 or V3.0. The default SDF version is 3.0. Used in combination with the <code>-map_removal_to_hold</code> option.
<code>-view viewName</code>	Uses the early and late delays for the specified analysis view to populate the <code>min</code> and <code>max</code> SDF triplet slots, when in multi-mode multi-corner analysis mode. The SDF <code>typ</code> slot remains empty (<code>earlyVal :: lateVal</code>). In multi-mode multi-corner analysis mode, if you want to use SPEF information when calculating the delays, you must use <code>read_spef -rc_corner</code> to import the SPEF files for each RC corner in the design.

<code>-voltage</code>	Defines the voltage values that will appear in the header of the generated SDF file. Use the colon delimiter to specify multiple voltage values. For example: <pre>-voltage 1.980:1.800:1.620</pre> In the above example, the header of the generated SDF file will contain: <pre>(VOLTAGE 1.980:1.800:1.620)</pre>
<code>-worst_case_illegal_cond_arcs</code> <i>string</i>	Specifies the <code>sdf_cond</code> - all, none, delays, or checks - for the arcs. When this parameter is specified, the <code>write_sdf</code> command detects illegal SDF condition syntax coming from the Liberty library and generates an unconditional annotation in the SDF file that worst-cases the delays of the related timing arcs. This prevents downstream tools (such as, Verilog simulators) from complaining about illegal syntax in the SDF file.

Definition of -edges Option Values

	edged Value	lib rary V al ue	no ed ge V al ue
--	--------------------	---	---

IOPATH from a unate input pin to output pin	No edge specifier	No edge specifier	No edge specifier
IOPATH from a non-unate input pin to output pin	Edge specifier at the input pin	Edge specifier at the input pin when specified	No edge specifier. When mergedged paths,

is either "b_o_t_h_-_e_d_g_e_s" or "s_t_a_r_t_-_e_d_g_e"; the maximum values are used for MAX and TYP fields; minimum values are

			e u s e d f o r M I N f i e l d s
IOPATH of a clock/enable pin to data out pin	Edge specifier at the input pin	E d g e s p e c i f i e r a t t h e i n p u t p i n w h e n s d f — e d g e s	N o e d g e s p e c i f i e r

		is either "both edges" or "start-edge"	
Timing Checks	Edge specifiers match the check arcs specified in the timing library	Overridden by value of the s d	Only the edges specified of the

referenced signals at tribute For both edges, the timing checks will contain

ent, respectively, of the Verilog-XL's \$hold() and \$setup system tasks

Examples

- The following command writes out an SDF 2.1 compliant output file named *my.sdf* with 4 digits after the decimal point:

```
tempus> write_sdf -version 2.1 -precision 4 my.sdf
```

The following SDF file output shows a comparison between the output of `-edges edged` with `-edges noedge`:

```
(HOLD (posedge D) (posedge CK) (-0.14:-0.14:-0.14))  
(HOLD (negedge D) (posedge CK) (-0.06:-0.06:-0.06))  
(SETUP (posedge D) (posedge CK) (0.22:0.22:0.22))  
(SETUP (negedge D) (posedge CK) (0.41:0.41:0.41))
```

When the `-edges` parameter is set to `noedge`, only the edge specifiers of the clock pin will be written, as shown below:

```
(HOLD D (posedge CK) (-0.14:-0.06:-0.06))  
(SETUP D (posedge CK) (0.22:0.41:0.41))
```

- The following command writes out the delta delay values for the analysis view to the specified SDF file:

```
write_sdf -delta_delay -view view1 tst.sdf
```

- The following command writes non-derated delays to the specified SDF file:

```
write_sdf tst.sdf -no_derate
```

Related Commands

- `read_sdf`

write_timing_context

```
write_timing_context  
[-help]  
[dir_name]  
[-instances instance_list]  
-module module_name  
[-overwrite]  
[-skip_interface_paths]
```

Writes the timing context model of the specified lower level modules/instances in the given output directory. Within this directory, Tempus creates sub-directories for each of the specified modules and writes the context model of each module within the corresponding sub-directory.

Parameters

-help	Prints out the command usage.
dir_name	Specifies the name of the output directory.
-instances instance_list	Specifies the instance list. If not specified, then context of all the instances of modules (specified with the -module parameter) will be generated.
-module module_name	Specifies the name of the module. You can use this parameter to write timing context information or the required lower level block modules. The timing context information for multiple modules can be written by specifying more than one module name.
-overwrite	Allows the software to overwrite any existing context directory data. If the context output directory already exists, the software will issue an error.
- skip_interface_paths	Skips the interface paths. However, the context data impacting only the internal reg-reg paths is preserved. During context analysis, the interface paths will be unconstrained.

Examples

- The following command will write the context model of block module `tdsp_core` and `results_conv` in respective sub-directories under the context directory `context/tdsp_core`

`context/results_conv:`

```
write_timing_context -module {tdsp_core results_conv} context
```

Since the `-instance` parameter is not specified with the `write_timing_context` command, the output directory will contain context models of all the instances of `tdsp_core` and `results_conv` modules.

- The following command will write context for `tdsp_core_inst1` instance of `tdsp_core` module and all the instances of `results_conv` module.

```
write_timing_context -module {tdsp_core results_conv} -instances {tdsp_core_inst1}  
context
```

Related Commands

- `read_timing_context`
- `set_timing_context_view_mapping`
- `report_timing_context_clock_mapping`
- `compare_timing_context`

write_timing_windows

```
write_timing_windows  
[-help]  
out_file  
[-pin]  
[-power_compatible]  
[-ssta_sigma_multiplier value]  
[-view viewName]  
[-voltage_threshold {lower_threshold upper_threshold}]
```

Generates a Timing Window File (TWF). The TWF file primarily contains the earliest and latest possible arrival times for a signal on a net or a pin.

The format of a timing window file consists of eight pairs of data as given below:

```
(NET <netname>
```

```
minRTW:maxRTW minRt:maxRt minRDr:maxRDr minRSlk:maxRSlk minFTW:maxFTW minFt:maxFt  
minFDr:maxFDr minFSlk:maxFSlk)
```

Where:

- minRTW: Minimum rise arrival time
- maxRTW: Maximum rise arrival time
- minRt: Minimum rise transition time
- maxRt: Maximum rise transition time
- minRDr: Minimum rise source resistance
- maxRDr: Maximum rise source resistance
- minRSlk: Minimum rise slack time
- maxRSlk: Maximum rise slack time
- minFTW: Minimum fall timing window
- maxFTW: Maximum fall timing window
- minFt: Minimum fall transition time
- maxFt: Maximum fall transition time
- minFDr: Minimum fall source resistance
- maxFDr: Maximum fall source resistance
- minFSlk: Minimum fall slack time
- maxFSlk: Maximum fall slack time

Parameters

<code>-help</code>	Prints out the command usage.
<code>out_file</code>	Writes the TWF file to the specified file name. The <i>filename</i> parameter must be the last argument in the list. Note: To write a compressed file, add the <code>.gz</code> extension to the file name.
<code>-pin</code>	Generates a TWF for each pin instead of each net. <i>Default:</i> Generates a TWF for the crosstalk analysis tool, which contains timing windows on each net.
<code>-power_compatible</code>	Generates a timing windows file that is suitable for power analysis.
<code>-ssta_sigma_multiplier value</code>	Specifies a sigma multiplier between 0 and 3. The value that you specify increases the arrival window by that amount and worst slack value is generated. The transition and impedance values are not impacted.
<code>-view viewName</code>	Generates a TWF for the specified multi-mode multi-corner view only. You must be multi-mode multi-corner analysis mode to use this parameter. If the <code>-view</code> parameter is not specified, then by default the first active view will be used to generate timing windows.
<code>-voltage_threshold</code> <code>{lower_thresholdupper_threshold}</code>	Specifies voltage threshold values for generating a Timing Window File (TWF). All the slews in the TWF file will be scaled with these values. The lower threshold value must be less than the higher threshold value. <i>Value range:</i> 0 to 100

Examples

- The `write_timing_windows -voltage_threshold {20 80}` command outputs the following in the TWF file:
(VOLTAGE_THRESHOLD 20 80)
- When active clocks are set using the `set_active_clocks` command, the `write_timing_windows` command will not display windows for inactive clocks in the output. The example report is shown below:

```

Related Commands

- `write_twf`
- `read_twf`

write_twf

```
write_twf  
-help  
outfile  
[-exclude_instances string]  
[-format string]  
[-include_instances string]  
[-include_lib_cells string]  
[-pin]  
[-power_compatible]  
[-ssta_sigma_multiplier float]  
[-third_party_file_format string]  
[-view string]  
[-voltage_threshold string]
```

Generates a timing window file (TWF). The TWF file mainly contains the earliest and the latest possible arrival times that a signal may arrive on a net or a pin.

The format of a timing window file consists of eight pairs of data as given below:

```
(NET <netname>
```

```
minRTW:maxRTW minRt:maxRt minRDr:maxRDr minRSlk:maxRSlk minFTW:maxFTW minFt:maxFt  
minFDr:maxFDr minFSlk:maxFSlk)
```

Where:

- minRTW: Minimum rise arrival time
- maxRTW: Maximum rise arrival time
- minRt: Minimum rise transition time
- maxRt: Maximum rise transition time
- minRDr: Minimum rise source resistance
- maxRDr: Maximum rise source resistance
- minRSlk: Minimum rise slack time
- maxRSlk: Maximum rise slack time
- minFTW: Minimum fall timing window
- maxFTW: Maximum fall timing window
- minFt: Minimum fall transition time
- maxFt: Minimum fall transition time
- minFDr: Minimum fall source resistance

- `maxFDr`: Maximum fall source resistance
- `minFSlk`: Minimum fall slack time
- `maxFSlk`: Maximum fall slack time

Parameters

<code>-help</code>	Prints out the command usage.
<code>-exclude_instances</code> <i>string</i>	Specifies a list of hierarchical instances to be excluded from the TWF file.
<code>-format</code> <i>string</i>	Specifies the name of the format to be used for TWF generation. Note: This parameter supports third-party TWF generation.
<code>-include_instances</code> <i>string</i>	Specifies a list of hierarchical instances to be included in the TWF file.
<code>-include_lib_cells</code> <i>string</i>	Specifies the library cells that require the input timing window.
<i>outfile</i>	Specifies the name of the output file. The <i>out_file</i> parameter must be the last argument in the list. To write a compressed file, add the <code>.gz</code> extension to the file name. Note: This parameter supports third-party TWF generation.
<code>-pin</code>	Generates a TWF for each pin instead of each net. <i>Default:</i> Generates a TWF for the crosstalk analysis tool, which contains timing windows on each net.
<code>-power_compatible</code>	Generates a timing window file (TWF) that is suitable for Power Analysis.
<code>-ssta_sigma_multiplier</code> <i>float</i>	Specifies a sigma multiplier between 0 and 3. The value that you specify increases the arrival window by that amount and worst slack value is generated. The transition and impedance values are not impacted.
<code>-third_party_file_format</code> <i>string</i>	Specifies the name of the third-party file format to be used during TWF generation. You can specify <code><ir_drop></code> or <code><jitter></code> format option. Note: This parameter supports third-party TWF generation.

<code>-view <i>string</i></code>	Specifies name of the analysis view. Note: This parameter supports third-party TWF generation.
<code>-voltage_threshold <i>string</i></code>	Specifies voltage threshold values for generating a Timing Window File (TWF). All the slews in the TWF file will be scaled to these values. The lower threshold value must be less than the higher threshold value. <i>Value range:</i> 0 to 100

Examples

- The `write_twf -voltage_threshold {20 80}` command writes the following in the TWF file:
(VOLTAGE_THRESHOLD 20 80)
- The following example shows third-party TWF report with IR drop option:

```
I m_clk__I10
S A 0.508 0.509 0.175 0.195
S Z 0.077 0.064 0.054 0.054
K Z -- -- -- --
T Z 1 -- -- 2.353 2.280 3 f
T Z 1 0.374 0.268 2.353 2.280 3 r
```

Third-party TWF report with Jitter option is shown below:

```
I m_clk__I10
T Z 1 -- -- 2.353 2.280 3 f
T Z 1 0.374 0.268 2.353 2.280 3 r
```

Where I - Instance, S - slew data, and K - slack data.

Distributed Static Timing Analysis Commands

- [distribute_launch_deferred_clients](#)
- [distribute_partition](#)
- [distribute_print_client_usage](#)
- [distribute_print_partition_stats](#)
- [distribute_start_clients](#)

distribute_launch_deferred_clients

distribute_launch_deferred_clients

[-help]

Launches the clients and waits for them to become available.

When the `distribute_start_clients -defer_launch` parameter is specified, the clients are not launched until the launch command is run.

The `distribute_launch_deferred_clients` command can be run at any point after `distribute_start_clients -defer_launch` option is specified, but should be specified no later than immediately after the `distribute_partition` command. Most commands after this point will require clients to be running.

Parameters

-help	Prints out the command usage.
-------	-------------------------------

Related Commands

- `distribute_start_clients`
- `distribute_partition`

distribute_partition

```
distribute_partition  
[-help]  
[-block_list string]  
[-cell string]  
[-cell_nohier string]  
[-exclude_block_list string]  
[-instance string]  
[-instance_nohier string]
```

Controls the method by which design partitioning is performed, and determines the scope of DSTA. This command tells the master process to start using the clients for partitioning. It is recommended to run the command after the parasitics are read in, thereby, enabling constraints, timing updates and reports to be shared between all the clients.

Parameters

-help	Outputs a brief description that includes type and default information for each <code>distribute_partition</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man distribute_partition</code> .
-block_list <i>string</i>	Specifies the list of blocks for partitioning. It lists the blocks that are to be analyzed in the incremental flow. This enables block-scope analysis in DSTA, therefore, only the specified blocks are analyzed in the run and all the other blocks are ignored.
-cell <i>string</i>	Specifies a list of instances of cells for partitioning.
-cell_nohier <i>string</i>	Specifies a list of instances of cells for partitioning excluding hierarchical children.
- exclude_block_list <i>block_names</i>	Specifies the list of blocks to exclude from the DSTA analysis in the incremental flow. This enables top-scope analysis in DSTA. All blocks that are not in this list are analyzed, along with the top-level of the design.
-instance <i>string</i>	Specifies a list of instances for partitioning.
-instance_nohier <i>string</i>	Specifies a list of instances for partitioning, excluding hierarchical children.

Examples

The following command specifies to perform a full-flat (non-incremental) flow:

```
dsta> distribute_partition
```

Related Commands

- `distribute_launch_deferred_clients`
- `distribute_start_clients`

distribute_print_client_usage

distribute_print_client_usage
[-help]

Reports CPU time, real time, current memory, and peak memory for all the clients. This command must be used instead of `report_resource` which is not capable of running in DSTA mode.

Parameters

- help	Outputs a brief description that includes type and default information for each <code>distribute_print_client_usage</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man distribute_print_client_usage</code> .
-----------	--

Related Commands

- `distribute_start_clients`
- `distribute_launch_deferred_clients`
- `distribute_partition`

distribute_print_partition_stats

```
distribute_print_partition_stats  
[-help]  
[-all]  
[-counts]  
[-resources]  
[-tcl_list]
```

Provides an estimate of the client memory requirements after partitioning, based on the instance count for each partition.

This command prints the partition statistics and estimated resource requirements after partitioning.

Parameters

-help	Prints out the command usage.
-all	Prints out instance and net counts by partition, overlap statistics, and resource requirements.
-counts	Prints out the instance and net counts by partition and overlap statistics.
-resources	Prints out the estimated memory and temp file size requirement by partition. This is the default behavior.
-tcl_list	Returns the requested statistics in a TCL list form. This parameter is supported with -resources.

Examples

- The following command shows the client resources:

```
distribute_print_partition_stats -resources
```

```
Active analysis views: 1
```

```
Partition 0 Estimated Memory: 50 GB. Estimated /tmp space: 60 GB.
```

```
Partition 1 Estimated Memory: 40 GB. Estimated /tmp space: 48 GB.
```

```
Partition 2 Estimated Memory: 50 GB. Estimated /tmp space: 60 GB.
```

```
Partition 3 Estimated Memory: 40 GB. Estimated /tmp space: 48 GB.
```

- The following command shows the instance count for each partition:

```
distribute_print_partition_stats -counts
```

Partition Stats:

```
Partition 0 instance-count: 13654609 extended instance-count: 4331968 (clustered:
4063874) outside clock instance-count: 320793
Partition 1 instance-count: 12983662 extended instance-count: 1153506 (clustered:
1045248) outside clock instance-count: 738683
Partition 2 instance-count: 14100713 extended instance-count: 4345271 (clustered:

clock net-count: 787647
Partition 2 net-count: 15970893 extended net-count: 1293759 (clustered: 1191587) outside
clock net-count: 419663
Partition 3 net-count: 14751488 extended net-count: 350045 (clustered: 306878) outside
clock net-count: 807687

Total nets: 59753864
Total partitioned nets: 59751874
Total instances: 52467900
Total partitioned instances: 52467832
Primary instance overlap: 2.34488%
Full instance overlap: 27.3563%(clustered: 26.113%)
```

When `-all` is specified, both the instance counts as well as client resources will be printed.

Related Commands

- `distribute_partition`
- `distribute_start_clients`
- `distribute_launch_deferred_clients`
- `distribute_partition`

distribute_start_clients

```
distribute_start_clients  
[-help]  
[-client_nowait]  
[-count integer]  
[-defer_launch | -minHost integer]  
[-no_log]  
[-no_logv]  
[-outdir string]  
[-overwrite]  
[-startup_script <string>]
```

Starts Tempus on distributed clients. This command starts the client processes. It requests LSF or SGE for a machine and starts to create a copy of Tempus on it. These client machines will be given tasks to do by the master machine.

Parameters

<code>-help</code>	Outputs a brief description that includes type and default information for each <code>distribute_start_clients</code> parameter. For a detailed description of the command and all of its parameters, use the <code>man</code> command: <code>man distribute_start_clients</code>.
<code>-client_nowait</code>	Specifies whether the master machine must wait for all the clients to be launched. When this parameter is specified, the master machine will continue to process, and will not wait for all the clients to be launched. However, the master will wait until partitioning occurs. Note: You cannot specify this parameter with the <code>-minHost</code> or <code>-defer_launch</code> parameter.
<code>-count <i>integer</i></code>	Specifies the number of clients. This parameter is used to set the number of clients when this value is not specified by the <code>set_multi_cpu_usage</code> command.
<code>-defer_launch</code>	Defers the launch of any clients unless the <code>distribute_launch_deferred_clients</code> command is issued explicitly. Note: This parameter cannot be used with the <code>-minHost</code> parameter.
<code>-minHost <i>integer</i></code>	Specifies the minimum number of available remote hosts (servers) that can be accepted.
<code>-no_log</code>	Does not allow the software to create a client log file.
<code>-no_logv</code>	Does not allow the software to create a verbose client log file.
<code>-outdir <i>string</i></code>	Specifies the base name of the client output directory.
<code>-overwrite</code>	Overwrites an existing <code>.log</code> file (and associated <code>.cmd</code> and <code>.logv</code> files), and does not add an integer to make the files unique.
<code>- startup_script <string></code>	When specified, the software will source the flowtool file on clients for attribute and object initialization.

Examples

- The following command starts client processes on 4 distributed clients:

```
dsta> distribute_start_clients -count 4 -outdir run1_output_dir
```

Path Exception Priorities - Overview

This section describes the path exception priority rules, which are followed by Tempus to determine the effective path exceptions to be applied on a particular path if multiple path exceptions are applied to it. The path exception priority rules are explained as per the path exception command type and various command parameters. The path exception commands are:

- `set_false_path`
- `set_max_delay`
- `set_min_delay`
- `set_multicycle_path`

Note: The priority rules (as explained in the following sections) are applicable to `set_path_adjust_group` and `group_path` commands also.

Priority Rules on the Basis of Path Exception Type

If the types of path exception commands are different, the priority order (in decreasing priority) is as follows:

1. `set_false_path`
2. `set_min_delay/set_max_delay`
3. `set_multicycle_path`

For example, `set_false_path -from A` is given priority over `set_multicycle_path -from A 2`.

Priority Rules on the Basis of Path Exception Command Reference Points

The path exception commands use parameters to specify reference points, such as, `-from/-through/-to/-clock_from/-clock_to`.

If there is more than one exception of a given type, for example the `set_multicycle_path` command, the path exception that is more specific has higher priority. A path exception has higher priority if it specifies more of the `-from/-through/-to` parameters. For example, the `-from -to` options will have priority over the `-from` option.

Here is an example of path exception priorities for `-from/-through/-to` parameters:

Priority	Path Exception
1 (highest)	<code>set_multicycle_path -from pins -through pins -to pins</code>
2	<code>set_multicycle_path -from pins -to pins</code>
3	<code>set_multicycle_path -from pins -through pins -to clocks</code>

If the path has the same number of reference points:

- `-from` and `-to` option has priority over the `-from` option
- `-from` option has priority over the `-to` option
- `-to` option has priority over the `-through` option

For example:

- i. `set_multicycle_path -from A 2` is given priority over `set_multicycle_path -through B 4`.
- ii. `set_false_path -from A` is given priority over `set_false_path -through B`.

2. If there are more than one exceptions of a given type with the same reference point, the path exception that is more specific has a higher priority. A path exception is more specific if it specifies a longer path than the other. For example, the '`-from -to`' parameters will have a higher priority over `-from`.

3. If a path exception differs only in terms of number of `-through` commands specified, the exception with a more constraining value will be honored.

Priority Rules on the Basis of `-start/-end` (only for `set_multicycle_path`)

For the `set_multicycle_path` constraint, if the reference points are the same and both the constraints differ only in `-start/-end`, the precedence rule is as follows:

- Command with `-start` will be higher priority, whereas `-end` will be lower priority.

Path Exception Priority Rules Table

The following table shows the priorities for path exceptions applied to the same path:

Path Exception Priorities

Priority	Path Exception
1. (Highest)	<code>set_false_path</code> <code>set_false_path -from pin_list</code> <code>set_false_path -to pin_list</code> <code>set_false_path -through pin_list</code>
2.	<code>set_max_delay -from pin_list</code>
3.	<code>set_max_delay -to pin_list</code>
4.	<code>set_max_delay -through pin_list</code>
5.	<code>set_max_delay -from clkwave_name</code>
6.	<code>set_max_delay -to clkwave_name</code>
7.	<code>set_max_delay</code> (The most constraining adjustment has the higher priority over less constraining adjustments.)
8.	<code>set_multicycle_path -from pin_list -to pin_list</code>
9.	<code>set_multicycle_path -from pin_list</code>
10.	<code>set_multicycle_path -to pin_list</code>
11.	<code>set_multicycle_path -through pin_list</code>
12.	<code>set_multicycle_path -from clkwave_name</code>
13.	<code>set_multicycle_path -to clkwave_name</code>
14. (Lowest)	<code>set_multicycle_path</code> (The most constraining adjustment has the higher priority over less constraining adjustments.)

Note: To check for applied/ignored path exceptions, you can use the following command:

```
report_timing -path_exceptions <applied | ignored | all>
```

To report all the path exceptions that have been ignored by timing analysis, you can use the following command:

```
report_path_exceptions [-ignored]
```

Examples of Path Exception Priorities

The following are examples of the path exception priorities for a path starting at **A**, going through **B**, and ending with **C**. The pairs of examples are ordered such that the highest priority constraint in one pair has precedence over the highest priority constraint in the next pair.

- In the following pair of constraints, the false path overrides the cycle addition for the path from **A** through **B** to **C**. For all other paths from **A**, the cycle addition applies.

```
set_false_path -from A -through B -to C
set_multicycle_path -from A 2
```
- In the following pair, the first constraint is applied (two cycles added) because the `-from` option has priority over the `-to` option:

```
set_multicycle_path -from A 3
set_multicycle_path -to C 2
```
- In the following pair, the first constraint is applied (two cycles added) because it specifies a `-through` pin as well as a `-to` pin:

```
set_multicycle_path -through A -to B 3
set_multicycle_path -to B 2
```
- In the following pair, the first constraint is applied (two cycles added) because the `-from` option has precedence over the `-to` option:

```
set_multicycle_path -from CLKA 3
set_multicycle_path -to CLKB 2
```
- In the following pair, the second constraint is applied because the second constraint overwrites the first one:

```
set_multicycle_path -from A 2
set_multicycle_path -from A 3
```

Bidirectional Pin Defaults

Bidirectional pins have both an input pin and an output pin type. This section explains the default pin type that the system uses for bidirectional pins.

Defaults for Pin (or Port) Constraints

The following defines the pin and port types that are used in the next table.

Bidirectional Pin (or Port) Type Definitions

Pin Type	Type 1	Type 2
----------	--------	--------

Blackbox pins	out	in
Instance pins	out	in
Netlist (primary) ports	in	out
Hierarchical ports	in	out

Bidirectional Pin Type Defaults

Pin or Port Constraint	Type	Hierarchical Port
<code>set_input_delay</code>	1	ignored
<code>set_output_delay</code>	2	ignored
<code>set_clock_latency</code>	1	ignored
<code>create_generated_clock</code>	1	used
<code>set_input_transition</code>	1	ignored
<code>set_driving_cell</code>	1	ignored
<code>set_drive</code>	1	ignored

Defaults for Port Constraints

The following table defines the port types that are used in the next table.

Bidirectional Port Type Definitions

Pin Type	Type 1	Type 2
Netlist (primary) ports	in	out
Hierarchical ports	in	out

Bidirectional Port Type Defaults

Port Constraint	Type	Hierarchical Port
<code>set_fanout_load</code>	2	ignored

<code>set_load</code>	2	ignored
<code>set_max_transition</code>	2	ignored

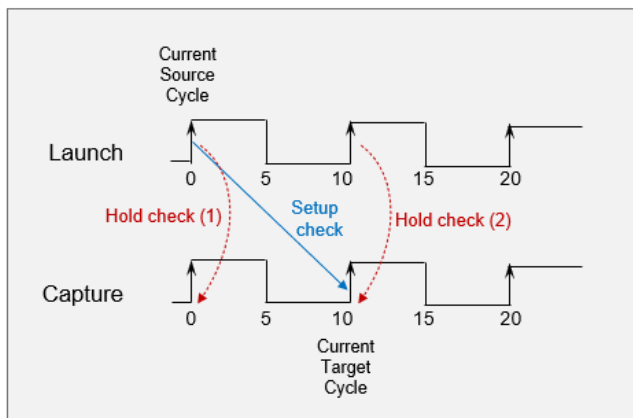

Cycle Accounting Rules - Data Checks

The following cycle accounting rules apply in the given below scenarios.

General Single-Cycle Timing

- When the launch and capture root clock edges align, the Setup capture edge is adjusted so that a full clock cycle is allowed for the path.
- When launch and capture Setup edges do not align, then the most constraining pair of root edges defines the cycle time. The launch and capture Hold edges are derived from the adjusted Setup edges:
 - Any multi-cycle adjustment to Setup is done before deriving the Hold edges.
 - Two Hold rules are checked and the most constraining edge pair is used (often they are the same).
 - Data launched from the current cycle at the source cannot be captured by the previous cycle at the target.
 - Data from the next cycle at the source cannot be captured by the current cycle at the target.
- Hold edges typically align - allowing full CPPR credit - including SI to be given.

The following diagram illustrates this behavior:

Zero-Cycle Timing

The zero-cycle Setup paths launch and capture data off of the same cycle. The zero-cycle Setup paths are obtained from the `set_data_check` constraint and non-sequential type library checks.

The following report outputs shows setup and hold data check output comparison:

Path 1: MET Data To Data Setup Check with Pin ref	
Endpoint:	data (v) checked with leading edge of 'PH10'
Beginpoint:	RB/Q (v) triggered by leading edge of 'PH10'
Other End Arrival Time	6.110
- Data Check Setup	3.000
+ Phase Shift	0.000
+ CPPR Adjustment	0.150
= Required Time	3.260
- Arrival Time	3.260
= Slack Time	0.000

Timing Point	Edge	Cell	Delay	Arrival Time
clk	^	-	-	0.000
C1/Y	^	BUF1	0.260	0.260
...				
data ->	v	-	0.000	3.260

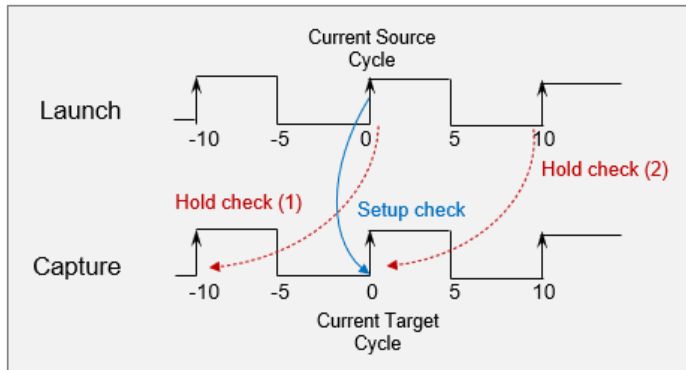

Timing Point	Edge	Cell	Delay	Arrival Time
clk	^	-	-	0.000
C1/Y	^	BUF1	0.110	0.110
...				
ref	^	-	0.000	6.110

Path 1: MET Data To Data Hold Check with Pin ref	
Endpoint:	data (v) checked with leading edge of 'PH10'
Beginpoint:	RB/Q (v) triggered by leading edge of 'PH10'
Other End Arrival Time	6.260
+ Data Check Hold	3.000
+ Phase Shift	-10.000
- CPPR Adjustment	0.100
= Required Time	-0.840
- Arrival Time	3.110
Slack Time	3.950

Timing Point	Edge	Cell	Delay	Arrival Time
clk	^	-	-	0.000
C1/Y	^	BUF1	0.110	0.110
...				
data ->	v	-	0.000	3.110

Timing Point	Edge	Cell	Delay	Arrival Time
clk	^	-	-	0.000
C1/Y	^	BUF1	0.260	0.260
...				
ref	^	-	0.000	6.260

The following diagram shows the default cycle accounting for a zero-cycle path:

Default cycle-accounting for 0-cycle path

In this case:

- The adjusted Hold edges mostly yield positive slack.
- The SI CPPR (50ps) is credited to Setup, but not Hold due to the Hold launch and capture edges not aligning.

Zero-Cycle Timing with Multi-Cycle Adjust

The following command will move the Hold launch back one cycle - making the Hold checks zero-cycle as well:

```
set_multicycle_path -1 -hold -to [get_ports data]
```

```
Path 1: MET Data To Data Setup Check with Pin ref
Endpoint: data (v) checked with leading edge of 'PH10'
Beginpoint: RB/Q (v) triggered by leading edge of 'PH10'
Other End Arrival Time      6.110
- Data Check Setup          3.000
+ Phase Shift               0.000
+ CPFR Adjustment           0.150
= Required Time             3.260

C1/Y	^	BUFX1	0.260	0.260
...				
ref	^	-	0.000	6.260

The current syntax does not restrict the multi-cycle application to only data-to-data checks.

Since both the Setup and Hold are zero-cycle, both receive the full CPFR credit - including SI.

The following diagram illustrates accounting for zero-cycle path when the above mentioned command is specified.

Accounting for 0-cycle path with: set_multicycle_path -1 -hold

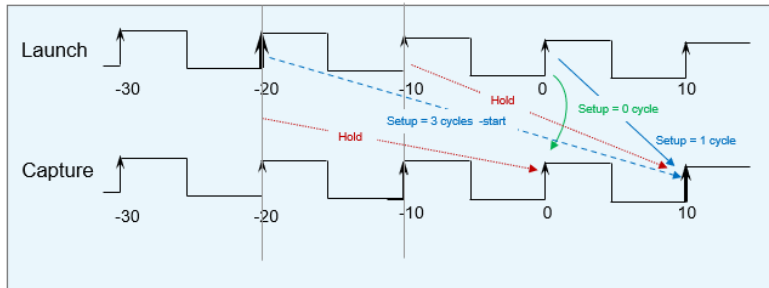

set_multicycle_path -start

When the set_multicycle_path -start parameter is used to adjust data-to-data paths, there might be some compatibility issues with third-party software.

You can set the timing_enable_sdc_compatible_data_check_mcp attribute to true to enable checking for

SDC compatible data checks. When the `-start` parameter is specified, the parameter reverses the reference clock by one clock cycle.

The following diagram shows Tempus cycle accounting when `set_multicycle_path -start 3` command is specified.

create_clock

```
create_clock  
-period period_value  
[-name clock_name]  
[-waveform edge_list]  
[-add]  
[-comment string]  
[source_objects]
```

Creates a clock object and defines its waveform in the current design. If you do not specify any *source_objects*, but you specify the `-name clock_name` argument, a virtual clock is created. The new clock has an ideal clock latency, and the software does not assume any propagation delay through the clock network.

The clock that you create using the `create_clock` command cannot have multiple pulses per period. You can specify multiple constraints on the same pin using the `-add` parameter.

If one of the *source_objects* is already the source of a clock, the source is removed from that clock. If you need to specify multiple clocks on the same source for simultaneous analysis, you must specify the `-add` parameter, to add this clock to the existing clock.

For example, if you specify the following command sequence, the PH2 clock waveform overwrites the PH1 waveform.:

```
create_clock -name PH1 ... [get_ports sysclk]
```

```
create_clock -name PH2 ... [get_ports sysclk]
```

To have both clocks applied, you must specify the following command sequence:

```
create_clock -name PH1 ... [get_ports sysclk]
```

```
create_clock -name PH2 -add ... [get_ports sysclk]
```

You can create a collection of clocks, which is a group of objects referenced by a string identifier using the [get_clocks](#) command.

Note: If the `create_clock` constraint is added incrementally in SI mode, an explicit `update_timing -full` command is required (before [report_timing](#) or [report_constraint](#)) for SI full accuracy.

Parameters

<code>-add</code>	Specifies multiple clocks on the same source for simultaneous analysis with different clock waveforms. You must specify the <code>-name</code> parameter with this parameter.
<code>-comment <i>string</i></code>	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
<code>-name <i>clock_name</i></code>	Specifies the string name of the ideal clock being created. If you do not specify this option, the clock gets the same name as the first clock source that you specify using the <code>-source_objects</code> option. If you do not specify any <code>source_objects</code> , you must specify the <code>-name <i>clock_name</i></code> option, which creates a virtual clock not associated with a port or pin.
<code>- period <i>period_value</i></code>	Specifies the value of the ideal clock in library time units.
<code><i>source_objects</i></code>	Specifies the list of pins or ports associated with an ideal clock waveform of the clock. If you do not specify this option, you must specify the <code>-name <i>clock_name</i></code> option, which creates a virtual clock not associated with a port or pin. If you specify a clock on a pin that already has a clock, the new clock replaces the old one.
<code>- waveform <i>edge_list</i></code>	Specifies the rise and fall edge times of the clock waveforms in library time units over an entire clock period. The first value in the edge list is the time at which the first transition on the clock occurs, which is the first rising transition after time zero, and edges are monotonically increasing. The numbers should represent one full clock period. If you do not specify the <code>-waveform <i>edge_list</i></code> option, a default waveform is assumed, and the leading edge is placed at 0 and the trailing edge is placed at the midpoint of the period, such that a symmetric clock is generated.

Examples

- The following command creates an `ideal_clk1` clock on port `clkA` with a period of 5, a rise at 0, and a fall at 2.5:

```
create_clock [get_ports {clkA}] -name ideal_clk1 -period 5 -waveform {0 2.5}
```
- The following command creates an `ideal_clk2` clock on port `clkB` with a period of 10, a rise at 1, and a fall at 9:

```
create_clock [get_ports {clkB}] -name ideal_clk2 -period 10 -waveform {1 9}
```

- `set_output_delay`

create_generated_clock

```
create_generated_clock
[-help]
target_pin_list
[-add]
[-comment string]
[-duty_cycle percent]
[-edge_shift edge_shift_list]
[-invert]
[-master_clock source_clock_name]
[-name <clock_name>]
[-preinvert]
-source source_pin
{[-multiply_by factor]
[-divide_by factor]
[-edges edge_list]
[-combinational]}
```

Creates a new clock signal from the clock waveform of a given pin in the design, and binds it with the pins or hierarchical pins in the *target_pin_list* argument. Whenever the source clock changes, the derived clock(s) change automatically.

You can generate a new clock waveform using one of the three ways:

- Multiply the frequency of the source clock
- Divide the frequency of the source clock
- Select the edges of the source clock to be mapped to the edges of the new clock

Given below are the SDC semantics to be used when the `create_generated_clock` command is defined:

- The edges are interpreted as alternating rise and falling edges.
- Each edge must be greater than and equal to its previous edge.
- Less than 3 edges are not allowed.
- Legal edge numbers start at “1”, edge 0 is undefined.
- Legal assertion of period 0 will be -edges {1 1 1 }.

If incorrect clock definitions are specified, an error will occur and the clock will not be generated.

When the `create_generated_clock` command is specified without the `-master_clock` parameter, and the software finds multiple clocks reaching the specified source pin, then the regular clocks are picked ahead of the generated clocks. In case if multiple regular clocks are present, the master clock is picked based on alphabetical sorting order of the clock names.

When this constraint is set on a pin, the software will stop the propagation of clock phases from all upstream clocks, including the generated clock's own master clock. The special latency-only phases of

the master clock may still be propagated to fulfill the requirements of other downstream generated clocks, which are used only for latency path calculations.

Note: A `create_generated_clock` assertion on a pin overrides any existing `create_generated_clock` assertion if both the constraints have the same source pin. In the following command sequence, the second assertion overrides the first:

```
create_generated_clock -name GCK1 -source CK -divide_by 2 U_FD1/Q
create_generated_clock -name GCK2 -source CK -multiply_by 2 U_FD1/Q
```

To have both assertions applied, you must specify the `-add` parameter. For example:

```
create_generated_clock -name GCK1 -source CK -divide_by 2 U_FD1/Q
create_generated_clock -name GCK2 -add -master_clock CLK -source CK -multiply_by 2 U_FD1/Q
```

Parameters

<code>-help</code>	Prints out the command usage.
<code>-add</code>	Models multiple generated clocks on the same source when multiple clocks must fan into the source pin. Ideally, one generated clock must be specified for each clock that fans into the master pin. Specify this parameter with the <code>-name</code> and <code>-master_clock</code> parameters. You can use the <code>-add</code> parameter to specify a different clock name for each generated clock, when used with the <code>-master_clock</code> option. Subsequently, you can use this clock name for setting other constraints, such as, <code>set_false_path</code> or <code>set_input_delay</code>.
<code>-combinational</code>	Restricts the path search for latency to only paths which do not cross sequential devices, or the source pins of other generated clocks. When you specify <code>-combinational</code>, if there are both sequential and combinational latency paths, the software only considers the combinational paths for the generated clock. If there are no combinational latency paths for the generated clock, the generated clock does not inherit latency from its parent clock hierarchy. By default, when calculating the latency of a generated clock, the software searches for the longest (and shortest) paths from the parent waveform to the generated clock point. All paths are considered, including those which traverse sequential elements such as flip-flops, registers, and latches. The default behavior is intended for cases where there is a cascade of generated clocks, and some of the clocks are not explicitly defined. The <code>-combinational</code> option can be used in conjunction with the <code>-multiply_by</code>, <code>-divide_by</code>, or <code>-edges</code> options.

<code>-comment string</code>	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
<code>-divide_by integer</code>	Determines the frequency of the new clock by dividing the frequency of the source clock by <i>dfactor</i> . For example, if <i>dfactor</i> =5, the new frequency is 1/5 of the source frequency, and the new clock period is 5 times the source clock period.
<code>-duty_cycle percent</code>	Sets the duty cycle (high pulse width or clock period). The number (<i>percent</i>) is between 0 and 100. For example, if <i>percent</i> =50, the high pulse width of the new clock waveform is the same as its low pulse width. Note: The <code>-duty_cycle</code> option can only be used with the <code>-multiply_by</code> option, otherwise it will be ignored with a warning.
<code>-edges edge_list</code>	Selects a list of edges from the source clock that form the edges of the derived clock. See the frequency division example below.
<code>-edge_shift edge_shift_list</code>	Specifies the amount of shift for each edge in the <i>edge_list</i> option.
<code>-invert</code>	Inverts the source clock. Use with the <code>-source</code> option and the <code>-multiply_by</code> or <code>-divide_by</code> options.
<code>-master_clock source_clock_name</code>	Generates a target clock from the specified clock name. If you specify the <code>-master_clock</code> option and multiple signals arrive at the source pin, the clock specified by this option is used to generate the target clock. Use the <code>-add</code> parameter along with <code>-master_clock</code> parameter to add a clock to the existing clock when you want to specify multiple clocks on the same source for simultaneous analysis.
<code>-multiply_by integer</code>	Determines the frequency of the new clock by multiplying the frequency of the source clock by <i>mfactor</i> . For example, if <i>mfactor</i> =4, the new frequency is 4 times the source frequency, and the new clock period is 1/4 of the source clock period.
<code>-name clock_name</code>	Specifies the name for the generated clock. <i>Default:</i> The system creates a name for you. Always specify a name for the generated clock. Some commands issue an error if you use the system-generated name.
<code>-preinvert</code>	Inverts the polarity of a master clock at the specified source pin.

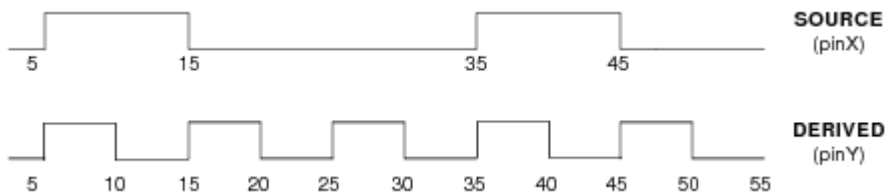

<code>-source</code> <i>source_pin</i>	Specifies the name of the source pin from which the generated clock is to be derived - with respect to the master clock containing the master clock as well as the generated clock definition.
<i>target_pin_list</i>	Specifies the list of pins where the generated clock assertion is applied. The clock signal propagating downstream from each of these pins becomes associated with the generated clock.

Examples

- The following command generates the derived clock waveform, as shown in the figure below:

```
tempus > create_generated_clock -name mult_3 -source pinX -multiply_by 3 -duty_cycle 50 pinY
```

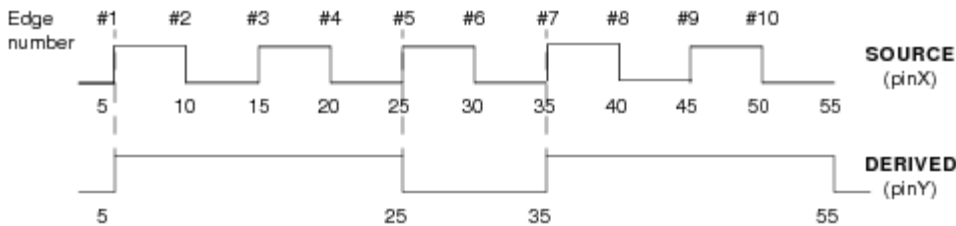

Figure: Derived Clock (Frequency Multiplication)

- The following command shows one way to create a divide-by-3 clock by using edge numbers of the source waveform to specify the new waveform, as shown in the figure below:

```
tempus > create_generated_clock -name genclk -source pinX -edges {1 5 7} pinY
```

Figure: Derived Clock (Frequency Division)

- The following command uses the `-divide_by` option to get the same clock period; the difference is in the duty cycle:

```
tempus > create_generated_clock -name div_3 -source pinX -divide_by 3 pinY
```

With the `-edges` option, the above example creates a clock with a duty cycle of 67 percent (20/30). However, using the `-divide_by 3` option preserves the 50 percent duty cycle of the source clock as shown in the figure below:

Figure: Derived Clock (Frequency Division, 50 Percent Duty-cycle)

- Using the following commands, when there is more than 1 source clock, the tool creates the generated clock based on the source clock specified with the `-master` option: `create_clock -name c1 -period 10 [get_ports {ck} ] -add`
`create_clock -name c2 -period 10 [get_ports {ck} ] -add`
`create_generated_clock -name newclk -source ck -divide_by 2 -master_clock c1 reg/Q -add`

Using the `report_clocks` command, the output waveform of the `newclk` clock is a divide-by-2 of the `c1` clock and is reported as shown in the example below.

Example: `report_clocks` after using the `-master` option

```
tempus > create_clock -name CK1 -period 20 [get_ports {CLK1} ] -add
tempus > create_clock -name CK2 -period 10 [get_ports {CLK1} ] -add
tempus > create_generated_clock -name GCLK -source CLK1 -divide_by 2 u8/Q -add -master_clock CK2
```

```
tempus > report_clocks
```

Clock Descriptions

Attributes

Clock Name	Source	Period	Lead	Trail	Generated	Propagated
CK1	CLK1	20.000	0.000	10.000	n	n
CK2	CLK1	10.000	0.000	5.000	n	n

Generated-Clock Descriptions

Name	Generated Source (pin)	Master Source (pin)	Master-clock	Invert	Freq. Multiplier	Duty-Cycle	Edges	Edge-Shift
GCLK	u8/Q	CLK1	CK2	n	1/2	-	-	-

Related Commands

- `create_clock`
- `get_clocks`
- `report_clocks`
- `reset_generated_clock`

current_design

```
current_design
[-help]
[design_name]
```

Changes the current directory in the design hierarchy to the specified design and returns the path to the design.

If no design is specified, the command returns the top-level design.

Parameters

-help	Prints out the command usage
design_name	Specifies the name of the top design.

Related Commands

- `set_max_transition`
- `set_min_capacitance`
- `set_min_transition`
- `list_libraries`

current_instance

```
current_instance  
[-help]  
[hinst]
```

Sets the specified instance to be the current instance.

The design objects referenced by the subsequent commands will be relative to this instance and all the searches for design objects start from this point. If the design objects are referenced hierarchically, the specified instance is used as the root (top) of the hierarchy.

Parameters

<code>-help</code>	Prints out the command usage.
<code>hinst</code>	Specifies the name of the instance to be set as the current instance. When this parameter is not specified, the current instance is set to the top instance of the hierarchy.

Examples

- The following command sets the current instance to MAC/MULTI, then sets a constant on a register pin inside the hierarchical instance and later sets the current instance back to top:

```
current_instance MAC/MULTI  
set_case_analysis 0 [get_pins {reg6/SE}]  
...  
current_instance
```

Related Commands

- `set_case_analysis`

get_current_constraint_mode

```
get_current_constraint_mode  
[-help]
```

Determines the constraint mode that is being currently read.

This command can be used inside SDC constraint files which are shared across multiple constraint modes to conditionalize how the constraints are interpreted for specific modes.

group_path

```
group_path  
[-help]  
[-comment string]  
-name path_group_name  
-from from_list  
[-to to_list]  
[-through through_list]
```

Groups paths in a design, and identifies them with a path group name. You can use the path group names for reporting.

You cannot use `group_path` statements in the SDC file when the software is in MMMC mode. In this case a warning is issued. However, the software supports the `group_path` command in MMMC mode as a command outside of the SDC file. The path groups are considered to be global in nature and apply to all the views, and are not supported on MMMC mode-specific basis. The path groups are persistent through a `saveDesign` to `restoreDesign` sequence. They are saved in the `<saveDir>/mmmc/pathgroup.sdc` file of a MMMC save directory.

Note that if a path can be included in multiple path groups, it will only be included in the path group with the most specific definition (`-from ... -through ... -to ...` is more specific than `-from ... -to ...` is more specific than `-from ...`).

Parameters

<code>-help</code>	Prints out the command usage.
<code>-comment <i>string</i></code>	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
<code>-from <i>from_list</i></code>	Specifies a list of pins, instances, or clocks that are the start of the paths. When you specify a clock object, all paths that are triggered by the clock are included in the path group.
<code>-name <i>path_group_name</i></code>	Specifies the name of the path group. If the <code>path_group_name</code> already exists, the specified paths are added to the existing path group.
<code>-through <i>through_list</i></code>	Specifies the pins or instances where the paths go through. When you specify multiple through list, the paths that go through the objects in the specified order are added to the path group.
<code>-to <i>to_list</i></code>	Specifies a list of pins, instances, or clocks where the path ends. You must specify valid endpoints in the <code>to_list</code> or else the software ignores the constraint. When you specify a clock object, all paths that are checked by the clock are included in the path group. If you specify an instance name in the <code>to_list</code> , all the data input pins of the instance are added to the path group.

Examples

- The following example groups paths that start from specific pins and end at the D pin of any instances whose name start with the string ff. The example also reports the specified path groups:

```
tempus > group_path -name path1 -from {ff1/CLK ff2/CLK} -to {ff*/D}  
tempus > report_timing -path_group path1
```

- The following command groups paths that go through specific points.

```
tempus > group_path -name path2 -through an1/Z -through an2/Z -through an3/Z
```

- If path group definitions are matching/overlapping (when the `-from/-through/-to` parameters are used), then path group resetting is applied. The path group overwriting and prioritization rules are similar to path exceptions.

The following examples show how path group resetting is applied.

If the timing path from u1/CK to u2/CK is part of both the path groups, then the path will be reported in the second path group only (that is, the most recent matching path group).

```
group_path -name g2 -from u1/CK,u4/Y -to u2/CK  
group_path -name g1 -from u1/CK -to u2/CK
```

In the following example, the path groups are not overlapping and have different `-from/-thru/-to` and map to the same path, then the path will be reported only in the first path group (that is, the most specific matching path group):

```
group_path -name g2 -from u1/CK -to u2/CK  
group_path -name g1 -to u2/CK
```

In this case, the path will be reported only in the first path group (that is, the most specific matching path group).

Related Commands

- `report_timing`
- `get_path_groups`
- `reset_path_group`
- `report_path_groups`
- `create_basic_path_groups`

reset_annotated_check

```
reset_annotated_check
[-help]
[-clock [rise | fall]]
[-cond sdf_condition]
[-setup | -recovery]
[-hold | -removal]
[-nochange_high | -nochange_low]
[-rise] [-fall]
{[[-from from_pins][-to to_pins]] | -all}
[obj_list]
```

Removes annotated timing check values that you had set by using the `set_annotated_check` command or by SDF annotation.

Note: The `reset_annotated_check` command does not reset the timing check values set by SDF annotations.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-all</code>	Resets all annotated timing check values in the design.
<code>-clock [rise fall]</code>	Specifies the direction of the related pin of the check to reset. <i>Default:</i> Resets checks against both edges of the clock
<code>-cond sdf_condition</code>	Resets all annotated timing check values for which a condition is specified.
<code>-fall</code>	Restricts the reset to only affect the falling edge of the constrained pins. <i>Default:</i> Checks on both rising and falling signals are reset
<code>-from from_pins</code>	Specifies the beginning instance pin of the timing arcs for which the annotated check is reset. This is usually the reference (for example, clock pin) of the constraint. The selected timing arcs are those that have their source pins specified using this option and the sink pins specified using the <code>-to</code> option. If this option is not specified, only timing arcs whose sink pins are specified using the <code>-to</code> option are selected. You cannot use this parameter with <code>obj_list</code> parameter.
<code>-hold -removal</code>	Resets annotations on the hold or removal check type.

<code>-nochange_high</code> <code>-nochange_low</code>	Resets the annotations on the specified timing check type.
<code>obj_list</code>	Resets the annotated checks on specified list or collection of cell instances.
<code>-rise</code>	Restricts the reset to only affect the rising edge of the constrained pins. <i>Default:</i> Checks on both rising and falling signals are reset
<code>-setup</code> <code>-recovery</code>	Resets annotations on the setup or recovery check type.
<code>-to to_pins</code>	Specifies the terminating instance pin of the timing arcs for which the annotated check is reset. This is usually the constrained pin (data pin) of the check. The selected timing arcs are those that have their sink pins specified using this option and the source pins specified using the <code>-from</code> option. If this option is not specified, only timing arcs whose source pins are specified using the <code>-from</code> option are selected. You cannot use this parameter with <code>obj_list</code> parameter.

Examples

- The following command resets all the timing check annotations in the design:
`tempus > reset_annotated_check -all`
- The following command resets all timing check annotations on a particular cell:
`tempus > reset_annotated_check [get_cells BLK/BR1]`
- The following command resets specific checks on a specific instance:
`tempus > reset_annotated_check -setup -hold [get_cells BLK/BR2]`
- The following command resets checks on a specific timing check arc:
`tempus > reset_annotated_check -from BLK/BR1/CK -to BLK/BR1/D`

Related Commands

- `set_annotated_check`

reset_annotated_delay

```
reset_annotated_delay
[-help]
{[-all] | [[-from from_pins] [-to to_pins]] | [object_list]}
```

Resets annotated delay assertions that have been previously specified using the `set_annotated_delay` command. When you reset an annotated delay, the system uses the delays which are calculated from the original libs for the arc.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-all</code>	Resets all annotated delay assertions in the design.
<code>-from</code> <i>from_pins</i>	Specifies timing arcs for which the delay is reset. The selected timing arcs are those that have their source pins specified using this option and the sink pins specified using the <code>-to</code> option. If this option is not specified, only timing arcs whose sink pins are specified using the <code>-to</code> option are selected.
<i>object_list</i>	Resets the annotated delays on specified list or collection of cell instances.
<code>-to</code> <i>to_pins</i>	Specifies timing arcs for which the delay is reset. The selected timing arcs are those that have their sink pins specified using this option and the source pins specified using the <code>-from</code> option. If this option is not specified, only timing arcs whose source pins are specified using the <code>-from</code> option are selected.

Examples

- The following command resets all the annotated delay assertions in the design:
`reset_annotated_delay -all`
- The following command resets all the `set_annotated_delay` assertions applied on pins (either `from` or `to`) of instance `f0`:
`reset_annotated_delay f0`
- The following command resets the `set_annotated_delay` assertions with the `from` and `to` pin pair combination:
`reset_annotated_delay -from u1/Y -to u2/A`

Related Commands

- `set_annotated_delay`

reset_annotated_transition

```
reset_annotated_transition
[-help]
{-all | port_or_pin_list}
```

Resets annotated transitions previously asserted by the `set_annotated_transition` command.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-all</code>	Resets all annotated transitions in the design.
<code>port_or_pin_list</code>	Specifies a list of specific pins or primary ports to reset the transition.

Examples

- The following commands reset the `set_annotated_transition` constraint on an internal pin `pad/Y0`.
`reset_annotated_transition pad/Y0`

or

```
reset_annotated_transition [get_pins {pad/Y0}]
```

You can also specify a collection as the pin argument. For example:

```
reset_annotated_transition [get_pins pad/*]
```

- The following commands reset the `set_annotated_transition` constraint set on a port `in`:
`reset_annotated_transition in`

or

```
reset_annotated_transition [get_ports {in}]
```

Any `set_input_transition` constraint applied on the same port is not removed. This is applicable only for input ports, as `set_input_transition` cannot be applied on output ports.

- The following command resets all the `set_annotated_transition` constraints:
`reset_annotated_transition -all`

Related Commands

- `set_annotated_transition`

reset_aocv_stage_weight

```
reset_aocv_stage_weight  
[-help]  
port_list  
[-early]  
[-late]
```

Resets the existing stage weight values set for the specified ports.

Parameters

-help	Prints out the command usage.
-early	Resets weight for early paths.
-late	Resets weight for late paths.
<i>port_list</i>	Specifies a list or collection of input, output, and bidi ports for which stage weight values are to be reset.

Examples

- The following example resets the stage weight values of ports `clock1` and `out0`:
`reset_aocv_stage_weight [get_ports {clock1 out0}]`

Related Commands

- `set_aocv_stage_weight`

reset_case_analysis

```
reset_case_analysis  
[-help]  
port_pin_list
```

Removes the assertions set by the set_case_analysis command.

Parameters

-help	Prints out the command usage.
port_pin_list	Specifies the list of ports or pins for which the assertions are to be removed.

Examples

- The following commands sets the assertion to 0 and then resets them:

```
set_case_analysis 0 CM1/S0  
get_property [get_pins CM1/S0] constant_value
```

Returns a value of 0

```
reset_case_analysis [get_pins CM1/S0]  
get_property [get_pins CM1/S0] constant_value
```

Returns a value of NA

Related Commands

- [set_case_analysis](#)

reset_clock

```
reset_clock
[-help]
{-all | clock_list}
```

Removes previously created clock assertions.

Parameters

-help	Prints out the command usage.
-all	Removes all clocks in the design.
<i>clock_list</i>	Specifies the list of clocks for which the clock assertion is removed.

Examples

- The following commands reset a list of clocks and all clocks, and display the results using the `report_clocks` command:

```
tempus > report_clocks
```

Generates the following report:

```
-----
Clock Descriptions
-----
Attributes
-----

```

```
tempus> reset_clock [get_clocks CK1]
tempus> report_clocks
```

Clock Descriptions

Attributes

Clock Name	Source	Period	Lead	Trail	Generated	Propagated
CK2	CLK1	10.000	0.000	5.000	n	n

Generated-Clock Descriptions

Name	Generated Edge-Shift	Master Source (pin)	Master-clock Source (pin)	Invert	Freq. Multiplier	Duty-Cycle	Edges
GCLK4	u8/Q	CLK4	CLK_W_4	n	1/2	-	-

Related Commands

- [create_clock](#)
- [report_clocks](#)

reset_clock_exclusivity

```
reset_clock_exclusivity  
[-help]  
pin_name
```

Allows to reset the `set_clock_exclusivity` constraints applied on pins.

Parameters

<code>-help</code>	Prints out the command usage.
<i>pin_name</i>	Specifies the name of pins for which clock exclusivity constraints need to be reset.

Related Commands

- `set_clock_exclusivity`

reset_clock_gating_check

```
reset_clock_gating_check  
[-help]  
[-setup]  
[-hold]  
[-rise]  
[-fall]  
[-high | -low]  
[obj_list]
```

Resets the specified setup and hold values for clock gating checks to the default values.

Parameters

-help	Prints out the command usage.
-high -low	Resets the non-controlling value (high or low) of the clock.
-hold	Resets clock gating hold values.
-rise -fall	Resets the specified setup (or hold) value to the rising (or falling) signals on the specified pins.
-setup	Resets clock gating setup values.
obj_list	Specifies a list of clocks, instances, or pins for which clock gating checks are to be reset to default values. If the <i>obj_list</i> parameter is not specified, the clock gating check is reset on the current design.

Related Commands

- [set_clock_gating_check](#)

reset_clock_groups

```
reset_clock_groups  
[-help]  
{-physically_exclusive | -logically_exclusive | -asynchronous}  
{-name name_list | -all}
```

Resets clock groups that have been set using the `set_clock_groups` command.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-all</code>	Removes all physically exclusive, logically exclusive, or asynchronous clock groups in the design. Removes all the physically exclusive, logically exclusive, or asynchronous clock groups in the design. This parameter should be used with one of the parameters: <code>-logically_exclusive</code>, <code>-physically_exclusive</code>, or <code>-asynchronous</code> at one time, and should not be used with the <code>-name</code> parameter.
<code>-asynchronous</code>	Specifies the asynchronous clock groups to be removed. This parameter must be used with either <code>-all</code> or <code>-name</code> parameter.
<code>-logically_exclusive</code>	Specifies the logically exclusive clock groups to be removed. This parameter must be used with either <code>-all</code> or <code>-name</code> parameter.
<code>-name <i>name_list</i></code>	Specifies the previously defined names of clock groups to be removed. This parameter should be used with one of the parameters: <code>-logically_exclusive</code>, <code>-physically_exclusive</code>, or <code>-asynchronous</code> at one time.
<code>-physically_exclusive</code>	Specifies all the physically exclusive clock groups to be removed. This parameter must be used with either <code>-all</code> or <code>-name</code> parameter.

Examples

- The following command resets all physically exclusive clock groups in the design:

```
reset_clock_groups -physically_exclusive -all
```

- The following command resets physically exclusive clock group `CLKGRP0`:
`reset_clock_groups -physically_exclusive -name CLKGRP0`

Related Commands

- `set_clock_groups`

reset_clock_latency

```
reset_clock_latency  
[-help]  
[-source]  
[-clock clock_list]  
obj_list
```

Resets assertions made by previous `set_clock_latency` commands.

Parameters

-help	Prints out the command usage.
-clock <i>clock_list</i>	Specifies the list of clocks with which associated <code>set_clock_latency</code> constraints, at the pin level, are to be removed. Note: This parameter cannot be used with clocks specified using the <i>obj_list</i> parameter.
<i>obj_list</i>	Specifies a list of pins, ports, or clock objects for which the assertions are to be removed.
-source	Removes the source latency.

Examples

- The following commands show the use of the `reset_clock_latency` command to remove a leaf-level `set_clock_latency` assertion, after the clock tree has been put into propagated mode:

```
set_clock_latency 3.141 [get_pins BLK/BR2/CK]  
report_timing -to BLK/BR2/D -path_type full_clock
```

The following report is generated:

```
Path 1: MET Setup Check with Pin BLK/BR2/CK  
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'  
Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'  
Other End Arrival Time 3.141 <---  
- Setup 0.191  
+ Phase Shift 10.000
```

```
= Required Time 12.950
- Arrival Time 0.249
= Slack Time 12.701
...
```

```
set_propagated_clock [get_ports tclk]
report_timing -path_type full_clock -net -to BLK/BR2/D
```

The following report is generated:

```
Path 1: MET Setup Check with Pin BLK/BR2/CK
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
Other End Arrival Time 3.141 <-----
- Setup 0.191
+ Phase Shift 10.000
= Required Time 12.950
- Arrival Time 0.594
= Slack Time 12.356
...
```

In this example, setting the root of the clock tree to propagated mode is not sufficient to override the `set_clock_latency` assertion at the clock endpoint. You must use the `reset_clock_latency` command to remove the assertion, so that the register sees propagated clock timing.

```
reset_clock_latency [get_pins BLK/BR2/CK]
report_timing -path_type full_clock -net -to BLK/BR2/D
```

The following report is generated:

```
Path 1: MET Setup Check with Pin BLK/BR2/CK
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
Other End Arrival Time 0.345 <-----
- Setup 0.186
+ Phase Shift 10.000
= Required Time 10.159
- Arrival Time 0.588
= Slack Time 9.571
```

- The following commands show that `reset_clock_latency` is only effective when it is applied on the same object for which you had set the assertion using the `set_clock_latency` command:

Latency here is specified on a pin object:

```
set_clock_latency 3.141 [get_pins BLK/BR2/CK]
report_timing -path_type full -net -to BLK/BR2/D
```

The following report is generated:

```
Path 1: MET Setup Check with Pin BLK/BR2/CK
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
Other End Arrival Time 3.141 <-
- Setup 0.191
+ Phase Shift 10.000
= Required Time 12.950
- Arrival Time 0.249
= Slack Time 12.701
```

Resetting of the latency is done on a clock object and has no effect on downstream latencies specified on pin objects.

In this example, a `reset_clock_latency` on the clock waveform that is driving BLK/BR2/CK will have no effect.

```
reset_clock_latency [get_clocks WAVE]
report_timing -path_type full -net -to BLK/BR2/D
```

The following report is generated:

```
Path 1: MET Setup Check with Pin BLK/BR2/CK
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
Other End Arrival Time 3.141 <-
- Setup 0.191
+ Phase Shift 10.000
= Required Time 12.950
- Arrival Time 0.249
= Slack Time 12.701
```

Related Commands

- [set_clock_latency](#)

reset_clock_sense

```
reset_clock_sense  
[-help]  
[-all]  
| [[-clocks clock_list] pin_or_port_list]]
```

Resets clock sense constraint(s) specified using the `set_clock_sense` command.

Parameters

<code>-help</code>	Prints out the command usage.
<code>-all</code>	Resets all the specified <code>clock_sense</code> constraints.
<code>-clocks</code> <i>clock_list</i>	Specifies the list of clocks for which the clock sense constraints are to be removed. The clocks must have previously been defined using the <code>set_clock_sense -clock</code> parameter.
<i>pin_or_port_list</i>	Specifies the list or collection of cell output pins for which the clock sense constraints will be removed.

Examples

- The following command resets all the previously defined `clock_sense` constraints from a design:

```
tempus > reset_clock_sense -all
```

Related Commands

- `set_clock_sense`

reset_clock_transition

```
reset_clock_transition
[-help]
clock_list
```

Removes the clock transition assertions you had set on the specified list of clock waveforms.

Parameters

<code>-help</code>	Prints out the command usage.
<code>clock_list</code>	Specifies a list of clock waveforms for which the clock transition assertions are removed. The <code>clock_list</code> variable can be a Tcl list or collection of clock waveforms.

Examples

- The following commands set the clock transition assertions, and resets them and displays the results using the `report_timing` command:

```
set_clock_transition 0.123 [get_clocks WAVE]
report_timing -net -to BLK/BR2/D
```

Generates the following report

```
Path 1: MET Setup Check with Pin BLK/BR2/CK
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'

Related Commands

- `set_clock_transition`

reset_clock_tree_latency

```
reset_clock_tree_latency  
[-help]  
[obj_list]
```

Resets network clock latency set using the `set_clock_latency` command in the fanout of the specified clock or pins and ports. The `reset_clock_tree_latency` command resets the latency until the root pins of clocks and generated clocks.

Use this command after building the clock tree and setting the clock network from the root to propagated mode using the `set_propagated_clock` command.

Note: You can use the `reset_clock_tree_latency` command only on command line and command script. You cannot specify it in an SDC file.

Parameters

<code>-help</code>	Prints out the command usage.
<code>obj_list</code>	Specifies list of objects - pins, ports, or clocks for which latency will be reset.

Related Commands

- `set_clock_latency`

reset_clock_uncertainty

```
reset_clock_uncertainty
[-help]
[-setup]
[-hold]
[-half_cycle_jitter | -full_cycle_jitter]
{ {-from | -rise_from | -fall_from} clksig_from_list
  {-to | -rise_to | -fall_to} clksig_to_list
  | pin_or_clock_list
}
```

Removes the assertions that were made by previous `set_clock_uncertainty` commands.

Parameters

-help	Prints out the command usage.
{-from -rise_from -fall_from} <i>clksig_from_list</i>	Removes the assertions for uncertainty value for the specified list of launching clocks. Note: You must specify one of these parameters with one of the <code>-to</code> , <code>-rise_to</code> , or <code>-fall_to</code> parameters. You cannot use these parameters when pins are specified.
	<code>-fall_from</code>: Removes the uncertainty value only from the falling edge of the launching clocks.
	<code>-from</code>: Removes the uncertainty value from both the rising and falling edges of the launching clocks.
	<code>-rise_from</code>: Removes the uncertainty value only from the rising edge of the launching clocks.
-half_cycle_jitter -full_cycle_jitter	Removes or resets the clock source jitter assertion(s) of the specified type.

<code>pin_or_clock_list</code>	Removes the target uncertainty assertions from the specified list of clocks or pins. The uncertainty value is removed from the registers clocked by the target waveform, or register pins in the fanout of the specified pin. You can specify a list of clock names, or clock root pin or port names relative to the current module. You also can specify a collection of clocks, or clock root pins or ports. Note: You cannot use this parameter when any of the <code>-from</code> and <code>-to</code> parameter pairs are specified.
<code>-setup/-hold</code>	Specifies whether the clock uncertainty is removed for setup or hold checks. <i>Default:</i> Removes clock uncertainty for both setup and hold check.
<code>{-to -rise_to -fall_to} clk_sig_to_list</code>	Removes the uncertainty value from the specified list of capture clocks. Note: You must specify one of these parameters with one of the <code>-from</code>, <code>-rise_from</code>, or <code>-fall_from</code> parameters. You cannot use these parameters when pins are specified.
	• <code>-fall_to</code>: Removes the uncertainty value only from the falling edge of the capture clocks.
	• <code>-rise_to</code>: Removes the uncertainty value only from the rising edge of the capture clocks.
	• <code>-to</code>: Removes the uncertainty value from both the rising and falling edges of the capture clocks.

Examples

The following commands sets and resets the clock uncertainty assertions and displays the results using the `report_timing` command:

- ```
set_clock_uncertainty 0.345 -from [get_clocks VCLK] -to [get_clocks WAVE]report_timing -
net -from tin
Generates the following report:
Path 1: MET Setup Check with Pin TR1/BR1/CK
Endpoint: TR1/BR1/D (v) checked with leading edge of 'WAVE'
Beginpoint: tin (v) triggered by trailing edge of 'VCLK'
Other End Arrival Time 0.000
- Setup 0.192
```

```
+ Phase Shift 10.000
- Uncertainty 0.345 <---
= Required Time 9.463
- Arrival Time 5.877
= Slack Time 3.586
```

- `reset_clock_uncertainty -from [get_clocks VCLK] -to [get_clocks WAVE]report_timing -net -from tin`  
# Generates the following report:  
Path 1: MET Setup Check with Pin TR1/BR1/CK  
Endpoint: TR1/BR1/D (v) checked with leading edge of 'WAVE'  
Beginpoint: tin (v) triggered by trailing edge of 'VCLK'  
Other End Arrival Time 0.000  
- Setup 0.192  
+ Phase Shift 10.000  
= Required Time 9.808  
- Arrival Time 5.877  
= Slack Time 3.931

## Related Commands

- `set_clock_uncertainty`

# reset\_data\_check

```
reset_data_check
[-help]
{-from | -rise_from | -fall_from} pin_or_port_list
{-to | -rise_to | -fall_to} pin_or_port_list
[-setup]
[-hold]
[-clock clock_object]
```

Removes specified data-to-data checks that you have specified using the [set\\_data\\_check](#) command.

## Parameters

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| -setup/-hold                                               | <p>Specifies whether the data check to be removed is for setup or hold check. If you do not specify either -setup or -hold option, both setup and hold checks are removed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

```
-to | -rise_to | -
fall_to
pin_or_port_list
```

Specifies the constrained pins of data-to-data checks to be removed.

The *pin\_or\_port\_list* list can contain either object IDs or hierarchical names relative to the current module. Leaf design cells (instances) can also be specified.

Use only one `-to`, `-rise_to`, or `-fall_to` parameter per command.

By default, the `-to` parameters removes both the rising and the falling edges.

Using `-rise_to` parameter removes the rising edge of the signal on the to pins.

Using `-fall_to` parameter removes the falling edge of the signal on the to pins.

## Examples

- The following commands set and reset the data checks from `port30` to `port28`:

```
set_data_check 0.345 -rise_from port30 -to port28
report_timing -rise_from port30 -to port28
```

The following report is displayed:

```
Path 1: VIOLATED Data To Data Setup Check with Pin port30
Endpoint: port28 (v) checked with leading edge of 'PH1'
Beginpoint: U2/Q (v) triggered by leading edge of 'PH1'
Other End Arrival Time 0.465
- Data Check Setup 0.345
+ Phase Shift 0.000
= Required Time 0.120
- Arrival Time 0.309
= Slack Time -0.189
```

```
reset_data_check -rise_from port30 -to port28
report_timing -rise_from port30 -to port28
```

The following information is displayed:

```
No constrained timing paths with given description found.
Paths may be unconstrained (try '-unconstrained' option) or may not exist.
```

## Related Commands

- [set\\_data\\_check](#)

# reset\_disable\_clock\_gating\_check

```
reset_disable_clock_gating_check
[-help]
pin_or_inst_list
```

Enables clock gating checks for the specified instances or pins.

## Parameters

|                                      |                                                                          |
|--------------------------------------|--------------------------------------------------------------------------|
| <code>-help</code>                   | Prints out the command usage.                                            |
| <code><i>pin_or_inst_list</i></code> | Specifies the list of disabled pins or instances that are to be enabled. |

## Related Commands

- `set_disable_clock_gating_check`

# reset\_disable\_timing

```
reset_disable_timing
[-help]
[-from pin_name -to pin_name]
obj_list
```

Restores timing arcs that were disabled using the `set_disable_timing` command.

## Parameters

|                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Related Commands

- `set_disable_timing`
- `report_inactive_arcs`

# reset\_drive

```
reset_drive
[-help]
port_list
```

Resets the drive previously asserted with the `set_drive` command on input ports. The `reset_drive` command removes assertions for all rise/fall, minimum/maximum combinations for which the assertion exists.

## Parameters

|                        |                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------|
| <code>-help</code>     | Prints out the command usage.                                                             |
| <code>port_list</code> | Specifies a list of input or bidirectional ports for which the drive resistance is reset. |

## Related Commands

- `set_drive`

# reset\_driving\_cell

```
reset_driving_cell
[-help]
[-rise]
[-fall]
[-min]
[-max]
port_list
```

Resets the driving cell assertions applied with the `set_driving_cell` command for the given rise/fall, minimum/maximum combination on ports.

If `-rise`, `-fall`, `-min`, or `-max` parameters are not specified, the `reset_driving_cell` command resets the assertion for all rise/fall, minimum/maximum combinations for which the assertion exists.

## Parameters

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <code>-help</code> | Prints out the command usage.                                              |
| <code>-rise</code> | Specifies the rising drive assertions.                                     |
| <code>-fall</code> | Specifies the falling drive assertions.                                    |
| <code>-min</code>  | Specifies the early drive assertion.                                       |
| <code>-max</code>  | Specifies the late drive assertion.                                        |
| <i>port_list</i>   | Specifies a list of ports for which the driving cell assertions are reset. |

## Related Commands

- `set_driving_cell`

# reset\_generated\_clock

```
reset_generated_clock
[-help]
{-all | clock_list}
```

Removes generated clock assertions previously created using the `create_generated_clock` command.

To use the `reset_generated_clock` command you must specify the `set_interactive_constraint_modes` constraints for the applicable modes. You can also include these commands in the SDC constraint file - applicable only for the views that include that SDC.

**Note:** The generated clocks may originate from the library files dotlib - you can use `reset_generated_clock` from the command line, or add it to all the SDC files in use.

## Parameters

|                                |                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>-help</code>             | Prints out the command usage.                                                                                   |
| <code>-all</code>              | Removes all the generated clocks in the design.                                                                 |
| <code><i>clock_list</i></code> | Specifies the list of clocks (in collection format) for which the generated clock assertions are to be removed. |

## Examples

- Here are some examples.
  - The following command removes the generated clock assertions on all the generated clocks `RC/Q`:

```
tempus > report_clocks
```

# The following report is displayed:

# reset\_ideal\_latency

```
reset_ideal_latency
[-help]
[-min]
[-max]
[-rise]
[-fall]
pin_or_port_list
```

Resets the ideal latency constraints, specified using the `set_ideal_latency` command, on instance pins or ports.

## Parameters

|                         |                                                           |
|-------------------------|-----------------------------------------------------------|
| -help                   | Prints out the command usage.                             |
| -fall                   | Resets the ideal latency for the falling edge.            |
| -max                    | Resets the ideal latency for the maximum corner.          |
| -min                    | Resets the ideal latency for the minimum corner.          |
| <i>pin_or_port_list</i> | Resets a list of objects - instance pins, ports, or nets. |
| -rise                   | Resets the ideal latency for the rising edge.             |

## Related Commands

- `set_ideal_latency`

# reset\_ideal\_network

```
reset_ideal_network
[-help]
obj_list
```

Resets the ideal network constraints, specified using the `set_ideal_network` command, on pins, ports, or nets.

**Note:** The `reset_ideal_network` command applies to all the active views and is not view/mode-based.

## Parameters

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <code>-help</code> | Prints out the command usage.                             |
| <i>obj_list</i>    | Resets a list of objects - instance pins, ports, or nets. |

## Related Commands

- `set_ideal_network`

# reset\_ideal\_transition

```
reset_ideal_transition
[-help]
[-min]
[-max]
[-rise]
[-fall]
pin_or_port_list
```

Resets the ideal transition constraint, specified using the `set_ideal_transition` command, on instance pins or ports.

## Parameters

|                         |                                                           |

| <code>pin_or_port_list</code> | <p>Specifies a single or multiple pins or ports for which the input delay is reset. To specify multiple pins, enclose the list with curly braces (<code>{}</code>) and separate the pin information with white space.</p>                                                                                                                                                                                                                                                                                                                                                |
| <code>-rise</code>            | <p>Resets the input delay for the rising edge at the input port. If both <code>-rise</code> and <code>-fall</code> options are omitted, the input delay is reset on both the edges.</p>                                                                                                                                                                                                                                                                                                                                                                                  |

## Related Commands

- `set_input_delay`

# reset\_load

```
reset_load
[-help]
port_net_list
```

Resets the existing `set_load` assertions specified on nets or ports.

## Parameters

|                            |                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------|
| <code>-help</code>         | Prints out the command usage.                                                     |
| <code>port_net_list</code> | Specifies a list of nets or ports in the top cell for which assertions are reset. |

## Related Commands

- `set_load`

# reset\_max\_capacitance

```
reset_max_capacitance
[-help]
obj_list
```

Resets maximum capacitance limit specified (using the the `set_max_capacitance` command) on the objects in the object list. The valid objects in the object list are primary ports, clocks, and current design.

## Parameters

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <code>-help</code> | Prints out the command usage.                                                                |
| <i>obj_list</i>    | Specifies the list of ports, modules, and/or clock waveforms for which assertions are reset. |

## Related Commands

- `set_max_capacitance`

# reset\_max\_fanout

```
reset_max_fanout
[-help]
obj_list
```

Resets maximum fanout limit specified (using the `set_max_fanout` command) on the objects in the object list. The valid objects in the object list are input and bidirectional ports and current design.

## Parameters

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <code>-help</code> | Prints out the command usage.                                          |
| <i>obj_list</i>    | Specifies the list of ports or modules for which assertions are reset. |

## Related Commands

- `set_max_fanout`

# reset\_max\_time\_borrow

reset\_max\_time\_borrow

[-help]

*obj\_list*

Resets the specified maximum time borrow limit of the specified objects.

## Parameters

|                 |                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------|
| -help           | Prints out the command usage.                                                              |
| <i>obj_list</i> | Specifies the list of pins, instances, or clocks for which the time borrow limit is reset. |

## Related Commands

- `set_max_time_borrow`

# reset\_max\_transition

```
reset_max_transition
[-help]
obj_list
```

Resets the maximum slew (transition) limit specified using the `set_max_transition` command (from the SDC or the Tempus command line) on the objects in the given object list. The valid objects in the object list are primary ports, clocks, and current design.

The maximum transition limit that is set by the user overrides the dotlib value so that sharper slews are implemented on the timing sensitive nets, such as clocks. A violation due to the `set_max_transition` setting does not impact the timing accuracy.

**Note:** For command-line usage of this command, you need to use `set_interactive_constraint_modes`, for example,

```
set_interactive_constraint_modes [all_constraint_modes -active]
```

## Parameters

|                       |                                                                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>    | Prints out the command usage.                                                                                                                                                   |
| <code>obj_list</code> | Specifies the list (or collection) of ports, modules, and/or clock waveforms for which assertions are to be reset. For example, <code>reset_max_transition [get_ports *]</code> |

## Related Commands

- `set_max_transition`

# reset\_min\_capacitance

```
reset_min_capacitance
[-help]
obj_list
```

Resets minimum capacitance limit specified (using the `set_min_capacitance` command) on objects in the object list. The valid objects in the object list are primary ports, clocks, and the current design.

## Parameters

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <code>-help</code> | Prints out the command usage.                                                                |
| <i>obj_list</i>    | Specifies the list of ports, modules, and/or clock waveforms for which assertions are reset. |

## Related Commands

- `set_min_capacitance`

# reset\_min\_fanout

```
reset_min_fanout
[-help]
obj_list
```

Resets minimum fanout limit specified (using the `set_min_fanout` command) on the objects in the object list. The valid objects in the object list are the inputs, bi-directional ports, and the current design.

## Parameters

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <code>-help</code> | Prints out the command usage.                                          |
| <i>obj_list</i>    | Specifies the list of ports or modules for which assertions are reset. |

## Related Commands

# reset\_min\_pulse\_width

```
reset_min_pulse_width
[-help]
obj_list
[-high]
[-low]
[-waveform_aware_type {absolute | source_width_ratio | all}]
```

Resets minimum pulse width constraint on the specified input ports of the top cell and the specified modules.

## Parameters

|                                                                                          |                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                                                       | Prints out the command usage.                                                                                                                                                                                                                                                                               |
| <code>-low</code>                                                                        | Resets the minimum pulse width checks that are applied to low signal levels only.                                                                                                                                                                                                                           |
| <code>-high</code>                                                                       | Resets the minimum pulse width checks that are applied to high signal levels only.                                                                                                                                                                                                                          |
| <code><i>obj_list</i></code>                                                             | Specifies a list of pins or clock waveforms for which the minimum pulse width is to be reset. If the list is not specified, the minimum pulse width check applies to all the pins in the clock tree of the current design. If a clock waveform is specified, all the pins driven by the clock are affected. |
| <code>-<br/>waveform_aware_type<br/>{absolute  <br/>source_width_ratio<br/>  all}</code> | Resets the regular and waveform-aware pulse width assertions.                                                                                                                                                                                                                                               |

## Related Commands

- [set\\_min\\_pulse\\_width](#)

# reset\_min\_transition

```
reset_min_transition
[-help]
obj_list
```

Resets minimum slew (transition) limit specified (using the `set_min_transition` command) on the objects in the object list. The valid objects in the object list are primary ports, clocks, and current design.

## Parameters

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <code>-help</code> | Prints out the command usage.                                                                |
| <i>obj_list</i>    | Specifies the list of ports, modules, and/or clock waveforms for which assertions are reset. |

## Related Commands

- `set_min_transition`

# reset\_mode

```
reset_mode
[-help]
[-type cell]
mode_list
inst_list
```

Resets the Liberty timing library modes for a specified instance.

Library modes are set using the [set\\_mode](#) command. By default, all library modes in the timing library are active. If you specify one or more library modes using the `set_mode` command, only the timing arcs consistent with the specified mode(s) are active for the instance. All other library modes become inactive. When you reset the library mode for the instance, all library modes become active again.

## Parameters

|               |                                                                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help         | Prints out the command usage.                                                                                                                                                                                                                                       |
| inst_list     | Specifies the instances to which to reset the library modes.                                                                                                                                                                                                        |
| mode_list     | Specifies the name of the library modes to reset.                                                                                                                                                                                                                   |
| -type<br>cell | Resets the library mode at the instance level.<br><br><b>Note:</b> Setting the library mode at the instance level is the only form of <code>set_mode</code> that is currently supported. This parameter exists to support constraints coming from external sources. |

## Examples

- The following command specifies that only the timing arcs consistent with the `test_A` library mode are active for instances of `b1`:

The `test_A` library mode is made inactive.

```
tempus > set_mode test_mode [get_cells BUF]
```

The following command reports the status of all library modes associated with BUF 'b1'. It shows that `test_A` is active and `test_B` is inactive.

```
tempus > report_mode b1
```

```

Mode Group test_mode of b1

Mode Status Condition
Name

test_B Inactive !(Y)
test_A ACTIVE Y

```

The following command resets the library mode for instances of `b1` :

```
tempus > reset_mode test_A b1
```

If you generate a report of the library mode status for `b1`, it shows that both modes are now active:

```
tempus > report_mode b1
```

```

Mode Group test_mode of b1

Mode Status Condition
Name

test_B ACTIVE !(Y)
test_A ACTIVE Y

```

## Related Commands

# reset\_output\_delay

```
reset_output_delay
[-help]
port_or_pin_list
[-clock clock_name]
[-clock_fall]
[-fall]
[-level_sensitive]
[-max]
[-min]
[-rise]
```

Resets previously specified output delay assertions.

## Parameters

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -clock<br>clock_name | <p>Specifies the name of the clock.</p> <p><i>Default:</i> The asynchronous (@) clock.</p> <p>If you specify multiple clocks, an error occurs and the constraint is ignored.</p> <p>When you specify the -clock parameter, the constraints specified for a pin with matching -clock parameter are reset.</p> <p>If you do not specify the -clock parameter, all the constraints applied on the specified pin, with or without the -clock parameter specification, are reset.</p> |
| -clock_fall          | <p>Removes the assertions for the delay that is relative to the falling edge of the clock. You must specify the -clock parameter with this parameter.</p> <p><i>Default:</i> Removes the delay assertions relative to the rising edge.</p>                                                                                                                                                                                                                                       |
| -fall                | Resets the output delay for the falling edge at the output port. If both -rise and -fall options are omitted, the output delay is reset on both the edges.                                                                                                                                                                                                                                                                                                                       |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-level_sensitive</code> | <p>Resets output delay that is launched by a positive level sensitive latch.</p> <p>When you specify the <code>-level_sensitive</code> parameter, the command resets all the <code>set_output_delay</code> constraints specified with the <code>-level_sensitive</code> parameter.</p> <p>If <code>-level_sensitive</code> parameter is not specified, the constraints specified for the same pin, with or without the <code>-level_sensitive</code> parameter, are reset.</p> <p><b>Note:</b> You must specify the <code>-clock</code> parameter with this parameter.</p> |
| <code>-max</code>             | Removes the delay assertions that refer to the setup analysis. If you do not specify the <code>-max</code> parameter, the output delay assertions for both setup and hold analysis are removed.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-min</code>             | Removes the delay assertions that refer to the hold analysis. If you do not specify the <code>-min</code> parameter, the output delay assertions for both setup and hold analysis are removed.                                                                                                                                                                                                                                                                                                                                                                             |
| <code>pin_or_port_list</code> | Specifies a single or multiple pins or ports for which the output delay is reset. To specify multiple pins, enclose the list with curly braces ( <code>{}</code> ) and separate the pin information with white space.                                                                                                                                                                                                                                                                                                                                                      |
| <code>-rise</code>            | Resets the output delay for the rising edge at the output port. If both <code>-rise</code> and <code>-fall</code> options are omitted, the output delay is reset on both the edges.                                                                                                                                                                                                                                                                                                                                                                                        |

## Examples

- The following example sets the output delays for the output port Z. The output signal is required at Z at 2 units before the rising edge of clock Clk1, and at 2.5 units before falling edge of clock Clk2:

```
tempus > set_output_delay 2 Z -clock Clk1
tempus > set_output_delay 2.5 Z -clock Clk2 -clock_fall -add_delay
```

- The following command will reset the output delay for the rising edge of clock Clk2:

```
tempus > reset_output_delay Z -clock Clk2

report_timing -to_rise Z -clock_to Clk2
#####

- Z v - 0.000 0.165 -0.500

```

- The following command resets the output delay for clock Clk2 with respect to the falling edge:  
tempus > reset\_output\_delay Z -clock Clk2 -clock\_fall
- The following command will reset all the output delays with respect to all the edges for both the clocks - Clk1 and Clk2:  
tempus > reset\_output\_delay Z

## reset\_path\_exception

```
reset_path_exception
[-help]
[-exact]
[-type {false_path | multicycle | path_delay}]
[-rise]
[-fall]
[{-from | -rise_from | -fall_from} from_list]
[-ignore_clock_latency]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]
[-setup | -hold]
[-all]
```

Removes any previously set path exceptions (or path exception of the specified type) for the given paths. To remove all path exceptions, use the `-all` option with the `reset_path_exception` command.

## Parameters

|                                                                      |                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                                   | Prints out the command usage.                                                                                                                                                                                                                                                                                       |
| <code>-all</code>                                                    | Removes all path exceptions. This option cannot be used with the <code>-from</code> , <code>-through</code> and <code>-to</code> options.                                                                                                                                                                           |
| <code>-exact</code>                                                  | Forces exact matching of the constraints. When this parameter is specified, the reset settings ( <code>-from/-through/-to</code> ) match with the original constrained path settings.                                                                                                                               |
| <code>-fall</code>                                                   | Applies the assertion at the falling edge of the signal on the path endpoints.                                                                                                                                                                                                                                      |
| <code>{-from   -rise_from   -fall_from} from_list</code>             | Specifies pins at the start of the path exceptions that are to be reset.                                                                                                                                                                                                                                            |
| <code>-ignore_clock_latency</code>                                   | Resets the exceptions specified with the <code>set_max_delay/set_min_delay -ignore_clock_latency</code> parameter.                                                                                                                                                                                                  |
| <code>-rise</code>                                                   | Applies the assertion at the rising edge of the signal on the path endpoints.                                                                                                                                                                                                                                       |
| <code>{-through   -rise_through   -fall_through} through_list</code> | Specifies the pins that the path to be reset goes through.                                                                                                                                                                                                                                                          |
| <code>{-to   -rise_to   -fall_to} to_list</code>                     | Specifies pins at the end of the path exceptions that are to be reset.                                                                                                                                                                                                                                              |
| <code>-setup   -hold</code>                                          | Resets only the setup (or hold) paths.<br><br>The <code>-setup/-hold</code> parameters should be used to reset maximum or minimum delay that is set using the <code>set_max_delay</code> and <code>set_min_delay</code> commands.<br><br><i>Default:</i> Both <code>-setup</code> and <code>-hold</code> are reset. |
| <code>-type {false_path   multicycle   path_delay}</code>            | Removes only path exceptions of the specified type.<br><br><i>Default:</i> All path exception assertions are reset.                                                                                                                                                                                                 |

## Examples

- In the example below the rising path from R1 to R2 has three different path exceptions asserted on it - they are listed in priority from lowest to highest. As shown in the reports below, the false path is

the highest precedence and so no path is reported.

```
tempus > set_multicycle_path -from R1/CK -rise_to R2/D 2
tempus > set_max_delay 3 -from R1/CK -rise_to R2/D
tempus > set_false_path -from R1/CK -rise_to R2/D
tempus > report_timing -from R1/CK -rise_to R2/D
```

The following information is displayed:

No constrained timing paths with given description found.  
Paths may be unconstrained (try '-unconstrained' option) or may not exist.

```
tempus > report_path_exceptions
```

The following report is displayed:

```

From To Early Late

R1/CK ^ R2/D false false

```

To report ignored path exceptions, you can use the following command:

```
tempus > report_path_exception -ignored

From To Early Late

R1/CK ^ R2/D delay 3 ignored
R1/CK ^ R2/D add 0 ignored
R1/CK ^ R2/D add 1 ignored

```

- In this example, the false path exception is removed from the path. This causes the max path delay assertion to become active - as it is the next highest precedence.

```
tempus > reset_path_exception -from R1/CK -rise_to R2/D -type false_path
tempus > report_path_exceptions
```

The following report is displayed:

```

From To Early Late

R1/CK ^ R2/D delay 3
R1/CK ^ R2/D add 0

```

```
tempus > report_timing -from R1/CK -rise_to R2/D
```

The following report is displayed:

```
Path 1: MET Setup Check with Pin R2/CK

- Consider the following `set_false_path` constraint:

```
tempus > set_false_path -from {u1/Y u2/Y} -to {u3/Y}
```

When you specify `reset_path_exception -from {u1/Y}` command without the `-exact` parameter, the command outputs the following:

```
tempus > set_false_path -from {u2/Y} -to {u3/Y}
```

The command `reset_path_exception -from {u1/Y} -exact` outputs the following:

```
tempus > set_false_path -from {u1/Y u2/Y} -to {u3/Y}
```

In this case (when `-exact` parameter is used), the path exception is not reset because differential matching is not allowed.

# reset\_path\_group

```
reset_path_group
[-help]
[-name group_name]
[-all]
```

Removes the specified path groups, or removes all groups.

## Parameters

|                         |                                     |
|-------------------------|-------------------------------------|
| -help                   | Prints out the command usage.       |
| -all                    | Removes all path groups.            |
| -name <i>group_name</i> | Removes the named group completely. |

## Examples

- The following command removes the group named GRPA:  
tempus > reset\_path\_group -name GRPA

## Related Commands

- `group_path`
- `get_path_groups`
- `report_path_groups`

## reset\_pll\_timing

```
reset_pll_timing
[-help]
inst
-pll_output_clock clock name or ID
-pll_output_pin output pin name
```

Resets the phase locked loop (PLL) that is used to adjust the delay on the PLL output clock waveform.

### Parameters

|                                           |                                                                                            |
|-------------------------------------------|--------------------------------------------------------------------------------------------|
| -help                                     | Prints out the command usage.                                                              |
| <i>inst</i>                               | Specifies the instance on which we will search reference pin, feedback pin, or output pin. |
| -pll_output_clock <i>clock name or ID</i> | Specifies the PLL output clock.                                                            |
| -pll_output_pin <i>output pin name</i>    | Specifies the PLL output pin.                                                              |

### Related Commands

## reset\_propagated\_clock

```
reset_propagated_clock
[-help]
pin_or_clock_list
```

Removes the propagated clock assertion for the specified clock waveforms or pins.

The ideal or propagated status of clock endpoints in the fanout of the specified pin/clock list is determined by the remaining clock latency propagated clock assertions in the clock network.

When new analysis views are used, the new corners do not have the source latency updated as per the clock propagation (`update_io_latency`) settings, so a reset and re-calculation is required.

**Note:** You must specify `set_interactive_constraint_modes` constraint prior to running the `reset_propagated_clock` command.

## Parameters

|                                |                                                                                                                                                                                                                                          |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>             | Prints out the command usage.                                                                                                                                                                                                            |
| <code>pin_or_clock_list</code> | Specifies a list of pins or clocks for which you want to reset the clock propagation mode to ideal mode.<br><br>The <code>pin_or_clock_list</code> parameter can be a collection, however, no hierarchical pins are allowed in the list. |

## Examples

- The following command sets the CLK1 clock waveform to `propagated` mode:  
tempus > set\_propagated\_clock CLK1
- The following command resets the CLK1 clock waveform back to `ideal` mode:  
tempus > reset\_propagated\_clock CLK1
- The following commands set the CLK1 clock to `propagated` mode and then reports them:  
tempus > set\_propagated\_clock [get\_clocks CLK1]  
tempus > report\_clocks

The following report is displayed:

| Name                         | Generated    | Master       | Master-clock | Invert | Freq.     | Duty-Cycle | Edges |
| Edge-Shift                   | Source (pin) | Source (pin) | Multiplier   |        |           |            |       |
| GCLK3                        | u8/Q         | CLK3         | CLK3         | n      | 1/2       | -          | -     |

- The following commands reset the CLK1 clock to `ideal` mode and then reports them:

```
tempus > reset_propagated_clock [get_clocks CLK1]
tempus > report_clocks
```

The following report is displayed:

| Clock Descriptions |        |        |       |        |           |            |
|--------------------|--------|--------|-------|--------|-----------|------------|
| Attributes         |        |        |       |        |           |            |
| Clock Name         | Source | Period | Lead  | Trail  | Generated | Propagated |
| CLK1               | CLK1   | 20.000 | 0.000 | 10.000 | n         | n          |
| CLK2               | CLK2   | 25.000 | 0.000 | 12.500 | n         | y          |

# reset\_property

```
reset_property
[-help]
[-obj_type {object_type}]
{obj_list}
property_name
```

Resets user-defined properties on objects set using the `set_property` command.

## Parameters

|                                                      |                                                                                        |
|------------------------------------------------------|----------------------------------------------------------------------------------------|
| <code>-help</code>                                   | Prints out the command usage.                                                          |
| <code>obj_list</code>                                | Specifies a list of objects for which the property is to be reset.                     |
| <code>-obj_type</code><br><code>{object_type}</code> | Specifies the type of object on which the property is to be reset.                     |
| <code>property_name</code>                           | Specifies the name of the property for which the user-defined property is to be reset. |

## Examples

- The following command resets user-defined property `slk` from pins `C1/A`:  
`tempus> reset_property [get_pins C1/A] slk`

## Related Commands

- `get_property`
- `set_property`
- `define_property`

# reset\_pulse\_clock\_max\_transition

```
reset_pulse_clock_max_transition
[-help]
obj_list
[-transitive_fanout]
[-rise]
[-fall]
```

Resets the maximum pulse clock transition constraint specified (using the `set_pulse_clock_max_transition` command) on the pulse generator cells, pulse generator library cells, clocks, and/or current design.

## Parameters

|                                      |                                                                                                                                                                |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                   | Prints out the command usage.                                                                                                                                  |
| <code>-fall</code>                   | Resets transition limit value for falling transition.                                                                                                          |
| <i>obj_list</i>                      | Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design - for which the transition value is to be reset. |
| <code>-rise</code>                   | Resets transition limit value for rising transition.                                                                                                           |
| <code>-<br/>transitive_fanout</code> | Specifies the transition limit value for transitive fanout.                                                                                                    |

## Related Commands

- `set_pulse_clock_max_transition`

# reset\_pulse\_clock\_max\_width

```
reset_pulse_clock_max_width
[-help]
obj_list
[-transitive_fanout]
```

Resets the maximum pulse clock width constraint specified (using the `set_pulse_clock_max_width` command) on the pulse generator cells, pulse generator library cells, clocks, and/or current design.

## Parameters

|                                   |                                                                                                                                                                         |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                | Prints out the command usage.                                                                                                                                           |
| <i>obj_list</i>                   | Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design - for which the maximum pulse clock width is to be reset. |
| <code>[-transitive_fanout]</code> | Specifies the pulse width value for transitive fanout.                                                                                                                  |

## Related Commands

# reset\_pulse\_clock\_min\_transition

```
reset_pulse_clock_min_transition
[-help]
obj_list
[-transitive_fanout]
[-rise]
[-fall]
```

Resets the minimum pulse clock transition constraint specified (using the `set_pulse_clock_min_transition` command) on the pulse generator cells, pulse generator library cells, clocks, and/or current design.

## Parameters

|                                 |                                                                                                                                                                                    |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>              | Prints out the command usage.                                                                                                                                                      |
| <code>-fall</code>              | Resets transition limit value for falling transition.                                                                                                                              |
| <i>obj_list</i>                 | Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design - for which the minimum pulse clock transition value is to be reset. |
| <code>-rise</code>              | Resets transition limit value for rising transition.                                                                                                                               |
| <code>-transitive_fanout</code> | Specifies the transition limit value for transitive fanout.                                                                                                                        |

## Related Commands

- `set_pulse_clock_min_transition`

# reset\_pulse\_clock\_min\_width

```
reset_pulse_clock_min_width
[-help]
obj_list
[-transitive_fanout]
```

Resets the minimum pulse clock width constraint specified (using the `set_pulse_clock_min_width` command) on the pulse generator cells, pulse generator library cells, clocks, and/or current design.

## Parameters

|                                   |                                                                                                                                                                         |

| <code>-help</code>                | Prints out the command usage.                                                                                                                                           |
| <i>obj_list</i>                   | Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design - for which the minimum pulse clock width is to be reset. |
| <code>[-transitive_fanout]</code> | Specifies the pulse width value for transitive fanout.                                                                                                                  |

## Related Commands

- `set_pulse_clock_min_width`

# reset\_resistance

```
reset_resistance
[-help]
net_list
```

Resets the existing `set_resistance` assertions specified on nets.

## Parameters

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <code>-help</code> | Prints out the command usage.                                    |
| <i>net_list</i>    | Specifies a list of nets for which the wire resistance is reset. |

## Related Commands

- [set\\_resistance](#)

# reset\_sense

```
reset_sense
[-help]
[-all | [[-clocks clock_list] pin_or_port_list]]
```

Resets clock sense constraint(s) specified using the `set_sense` command.

## Parameters

|                                           |                                                                                                                                                                                        |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                        | Prints out the command usage.                                                                                                                                                          |
| <code>-all</code>                         | Resets all the specified <code>clock_sense</code> constraints.                                                                                                                         |
| <code>-clocks</code><br><i>clock_list</i> | Specifies the list of clocks for which the clock sense constraints are to be removed. The clocks must have previously been defined using the <code>set_sense -clocks</code> parameter. |
| <i>pin_or_port_list</i>                   | Specifies the list or collection of cell output pins or ports for which the clock sense constraints will be removed.                                                                   |

## Examples

- The following command resets all the previously defined `clock_sense` constraints from a design:

```
tempus > reset_sense -all
```

## Related Commands

- [set\\_sense](#)

# set\_active\_clocks

```
set_active_clocks
[-help]
active_clock_list | all_clocks
```

Defines a list of active clocks in the design.

When the `set_active_clocks` command is specified, only the specified clocks are made active while others remain inactive. Any clock created after using the `set_active_clocks` command is active by default. The following commands are impacted:

- `report_clocks` command output displays a new column showing active or inactive clocks in the design.
- `get_clocks` command will report all clocks including inactive clocks.
- `write_timing_windows` command will not display windows for inactive clocks in the output report.
- `get_property` command allows you to query on active clocks using the `is_clock_active` property.

## Parameters

|                                             |                                    |
|---------------------------------------------|------------------------------------|
| <code>-help</code>                          | Prints out the command usage.      |
| <code>active_clock_list   all_clocks</code> | Specifies a list of active clocks. |

## Examples

- The following command makes the specified clocks active while others remain inactive (only `Iclk1` is active, while `Iclk2` is inactive):

```
tempus > set_active_clocks Iclk1
```

## Related Commands

- `report_clocks`
- `get_clocks`
- `get_property`
- `write_timing_windows`

# set\_annotated\_check

```
set_annotated_check
[-help]
value
[-clock clock_check]
[-cond sdf_condition]
[-fall]
-from from_pins
[-incremental]
[-max]
[-min]
[-rise]
-to to_pins
{-setup | -hold | -recovery | -removal | -nochange_high | -nochange_low}
```

Annotates the setup, hold, recovery, or removal timing check value between two or more pins of a cell in the current design.

## Parameters

|                            |                                                                                                                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                      | Prints out the command usage.                                                                                                                                                                      |
| <i>value</i>               | Specifies the timing check value.                                                                                                                                                                  |
| -clock <i>clock_check</i>  | Specifies clock rising or falling.<br>Default: Sets checks for both clock rise and fall. Use the <i>clock_check</i> argument to specify rise or fall.                                              |
| -cond <i>sdf_condition</i> | Specifies the condition only if the library has a condition attached to the specified timing check arc. The <i>sdf_expression</i> must match the syntax of the condition specified in the library. |
| -fall                      | Specifies the data fall transition for the timing check.<br>Default: Sets both -rise and -fall.                                                                                                    |
| -from <i>from_pins</i>     | Specifies start points of the timing arcs for which checks are annotated. Use the <i>from_pins</i> argument to specify a list of leaf cell clock pins.                                             |
| -incremental               | Sets the incremental checks.                                                                                                                                                                       |

|                                                                                     |                                                                                                                                                                                             |
|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-max</code>                                                                   | Specifies the maximum timing check for both data rise and data fall transitions. Use this option only if the design uses minimum and maximum ( <code>min-max</code> ) operating conditions. |
| <code>-min</code>                                                                   | Specifies the minimum timing check for both data rise and data fall transitions. Use this option only if the design uses minimum and maximum ( <code>min-max</code> ) operating conditions. |
| <code>-rise</code>                                                                  | Specifies the data rise transition for the timing check.<br>Default: Sets both rise and fall.                                                                                               |
| <code>-setup   -hold   -recovery   -removal   -nochange_high   -nochange_low</code> | Specifies the timing check type. Make sure there is a corresponding timing arc between the <i>from_pins</i> and the <i>to_pins</i> arguments.                                               |
| <code>-to to_pins</code>                                                            | Specifies endpoints of the timing arcs for which checks are annotated. Use the <i>to_pins</i> argument to specify a list of leaf cell clock pins.                                           |

## Examples

- The following commands annotates a `nochange` check between data low and clock low. The `nochange` margin before the clock is 1.3 and the `nochange` margin after the clock is 2.4:  

```
set_annotated_check -nochange_low 1.3 -clock fall -fall -from {I1/CP} -to {I1/EN}
set_annotated_check -nochange_low 2.4 -clock fall -rise -from {I1/CP} -to {I1/EN}
```
- The following command annotates a 2.0 setup time between the CP clock pin and the A data pin of the `<instance_name>` instance:  

```
tempus > set_annotated_check -setup 2.0 -from <instance_name>/CP -to <instance_name>/A
```

## Related Commands

- `reset_annotated_check`
- `set_annotated_delay`

# set\_annotated\_delay

```
set_annotated_delay
[-help]
delay_value
[-cond expression]
[-delta_only]
[-fall]
[-increment]
[-max]
[-min]
[-rise]
{-net | -cell }
{[-from from_pins] [-to to_pins]}
```

Annotates delay to timing arcs. If you specify the `set_annotated_delay` command without any parameters, the delay value specified is assumed to include both the base delay and any delta (cross-talk) delay.

## Parameters

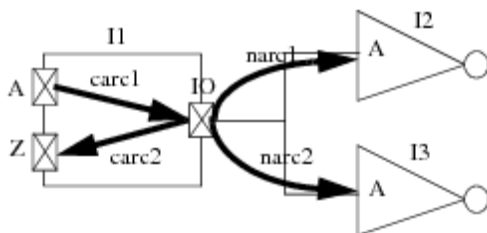

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-cond<br/>expression</code> | Specifies the sdf condition of the selected timing arcs.<br><i>Default:</i> The delay applies to all the timing arcs selected using the <code>-from</code> and the <code>-to</code> options. The expression is ignored for net arcs.<br><b>Note:</b> You cannot specify the <code>-cond</code> parameter with <code>-net</code> . If specified, an error is displayed.                                                                                                                                                                                                                                                                                                                                  |
| <code>value</code>                | Specifies the delay value to be annotated to the selected timing arcs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>-<br/>delta_only</code>     | Populates the incremental delay slot with the delay value, so that you can differentiate between the base net delay and a delay offset that is due to crosstalk. The software reports the incremental (or delta) delay value separately in the timing report using <code>report_timing -format incr_delay</code> , and maintains the separate value for CPPR calculations.<br><br>If the base delay was previously calculated or annotated from the SDF, the <code>-delta_only</code> parameter adds the specified delay to the existing base delay.<br><b>Note:</b> This parameter only can be used with the <code>-net</code> parameter; you cannot specify it with the <code>-cell</code> parameter. |

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-from</code><br><code>from_pins</code> | <p>Specifies timing arcs to which the delay applies. The selected timing arcs are those that have their source pins specified using this option and the sink pins specified using the <code>-to</code> option. If this option is not specified, only timing arcs whose sink pins are specified using the <code>-to</code> option are selected.</p> <p><b>Note:</b> You cannot specify hierarchical pins. If specified, an error message is displayed.</p>       |
| <code>-increment</code>                      | <p>Increments the specified delay value on top of the existing base delay value.</p>                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-min   -max</code>                     | <p>Specifies the annotated delay for a particular operating corner. You can apply the <code>-min</code> parameter to the minimum operating corner and the <code>-max</code> parameter to the maximum operating corner.</p>                                                                                                                                                                                                                                      |
| <code>-net   -cell</code>                    | <p>Specifies whether the delay should be annotated to cell arcs or net arcs.</p>                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-rise/-fall</code>                     | <p>Specifies the transition to which the delay applies. For cell arc, this is the output transition.</p> <p><i>Default:</i> The delay applies to both transitions.</p>                                                                                                                                                                                                                                                                                          |
| <code>-to</code><br><code>to_pins</code>     | <p>Specifies timing arcs to which the delay applies. The selected timing arcs are those that have their sink pins specified using this option and the source pins specified using the <code>-from</code> option. If this option is not specified, only timing arcs whose source pins are specified using the <code>-from</code> option are selected.</p> <p><b>Note:</b> You cannot specify hierarchical pins. If specified, an error message is displayed.</p> |

## Examples

- The following example shows the usage of `-cell` and `-net` options:

### Example Figure to Show How to Use the `-cell` and `-net` Options

- Use the `-cell` option to select the cell arc `carc2` only:  
`set_annotated_delay 3.0 -cell -from {I1/IO}`
- Use the `-net` arc option to select net arcs `narc1` and `narc2` only:

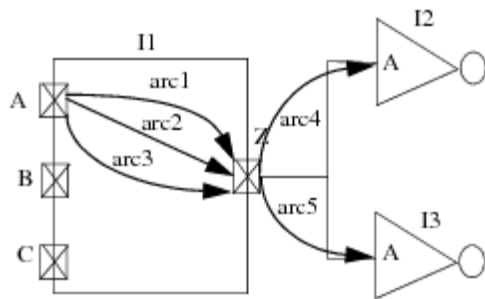

`set_annotated_delay 3.0 -net -from {I1/IO}`

- This TLF description is used for the following examples:

```
CELL (NAND3 // arc 1 Path(A => Z 10 01 DELAY(ioDelayRiseModel0)
SLEW(SlopeRiseModel0)) Path(A => Z 01 10 DELAY(ioDelayFallModel0)
SLEW(SlopeFallModel0)) // arc2 Path(A => Z 10 01 COND(B & C) SDF_COND(B & C)
DELAY(ioDelayRiseModel1) SLEW(SlopeRiseModel1)) Path(A => Z 01 10 COND(B & C)
SDF_COND(B & C) DELAY(ioDelayFallModel1) SLEW(SlopeFallModel1)) arc3 Path(A
=> Z 10 01 COND(~B | ~C) SDF_COND(!B | !C) DELAY(ioDelayRiseModel2) SLEW(SlopeRiseModel2)) Path(A
=> Z 01 10 COND(~B | ~C) SDF_COND(!B | !C) DELAY(ioDelayFallModel2)
SLEW(SlopeFallModel2)) . . . }
```

### Example Figure to Show How to Use the -from and -to Options

- The following command annotates a delay of 3.0 to arcs `arc1`, `arc2`, and `arc3` for the rise and fall transition at the pin `I1/Z`, for the two corners `{min typ max}`: `set_annotated_delay 3.0 -from A -to Z -cell`
- The following command annotates a delay of 2.5 to net `arc4` for both the rising and the falling transition and for the two corners `{min typ max}`: `set_annotated_delay 2.5 -from I1/Z -to I2/A -net`
- The following command annotates a delay of 1.5 to `arc2` for the rising transition and the min corner: `set_annotated_delay 1.5 -from I1/A -to I1/Z -rise -min -cond "B & C" -cell`
- The following commands annotate a delay of 3.0 to `arc1` and `arc2`, and a delay of 2.4 to the `arc3`: `set_annotated_delay 3.0 -from I1/A -to I1/Z -cell set_annotated_delay 2.4 -from I1/A -to I1/Z -cond {!B | !C} -cell`
- The following commands first annotate a delay of 3.0 to `arc1`, `arc2` and `arc3`, then overwrite the value set by the first `set_annotated_delay` command: `set_annotated_delay 2.4 -from I1/A -to I1/Z -cond {!B | !C} -cell set_annotated_delay 3.0 -from I1/A -to I1/Z -cell`

## Related Commands

- `reset_annotated_delay`
- `set_annotated_check`

# set\_annotated\_transition

```
set_annotated_transition
[-help]
[-rise | -fall]
[-min | -max]
value
pin_list
```

Sets the transition time to be annotated on specified ports or pins in the current design. The transition time that you specify using this command overrides the transition time calculated internally within the software. You can use this command to set the transition time of internal cell instance pins.

## Parameters

|                            |                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>         | Prints out the command usage.                                                                                                                               |
| <code>-min   -max</code>   | Specifies whether the transition value is set for minimum or maximum transition time.<br><i>Default:</i> Transition value is set for both transition times. |
| <code>pin_list</code>      | Specifies a list of pins or ports to be annotated with the transition time that you specify using the <i>value</i> parameter.                               |
| <code>-rise   -fall</code> | Specifies whether the transition value is set for rising or falling transition time.<br><i>Default:</i> Transition value is set for both transitions.       |
| <code>value</code>         | Specifies the transition time to be annotated to the selected pins or ports.                                                                                |

## Examples

- The following command annotates a transition time value of 0.6 on port A:  
tempus > set\_annotated\_transition 0.6 [get\_ports A]
- The following command annotates a transition time value of 0.7 on pin I2/A:  
tempus > set\_annotated\_transition 0.7 [get\_pins I2/A]
- The following command annotates a transition value of 0.7 on pin I2/A for rising transition time:  
tempus > set\_annotated\_transition -rise 0.7 [get\_pins I2/A]
- The following command annotates a transition value of 0.7 on pin I2/A for rising transition time and minimum pvt corner:  
tempus > set\_annotated\_transition -rise -min 0.7 [get\_pins I2/A]

## Related Commands

- `set_input_transition`
- `get_pins`

- `report_ports`
- `reset_annotated_transition`

## set\_aocv\_interface\_path\_offset

```
set_aocv_interface_path_offset
[-help]
derate_offset_value
[lib_cell_list]
[-view view_name]
[-delay_corner dc_corner_name]
[-cell]
[-net]
-power_domain power_domain_name_list
```

You can perform path-based inter power domain (IPD) timing analysis by specifying derate offset value for an entire power domain(s) and specific library cell(s) on paths crossing multiple power domains. This feature is supported for path-based analysis (PBA) mode only.

The `set_aocv_interface_path_offset` command allows you to specify the derate offset value for path segments crossing multiple power domains. The software adds the derate offset value to the AOCV derate value if the combined (AOCV + IPD offset) derate number causes pessimistic PBA timing slack value.

### Parameters

|                                                                   |                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                                | Prints out the command usage.                                                                                                                                                                                                                        |
| <code>-cell</code>                                                | It is a boolean option. When the <code>-cell</code> option is specified, intent is to apply “derate offset” only for that cell objects.<br><br>In absence of these options, derate offset value will be applied to both cell and net type of objects |
| <code>-delay_corner</code><br><code>dc_corner_name</code>         | Specifies a list of delay corners.                                                                                                                                                                                                                   |
| <code>derate_offset_value</code>                                  | Specifies value of derate offset.                                                                                                                                                                                                                    |
| <code>lib_cell_list</code>                                        | Specifies a list of library cells for a specific interface.                                                                                                                                                                                          |
| <code>-net</code>                                                 | It is a boolean option. When the <code>-net</code> option is specified, intent is to apply “derate offset” only for that net objects.<br><br>In absence of these options, derate offset value will be applied to both cell and net type of objects   |
| <code>-power_domain</code><br><code>power_domain_name_list</code> | Specifies a list of power domains.                                                                                                                                                                                                                   |

`-view view_name`

Specifies a list of views.

## Examples

- The following example specifies the offset derate value of `-0.6` for the power domain `{PD3 PD4}`:  
`set_aocv_interface_path_offset -0.6 -power_domain {PD3 PD4} -delay_corner V1_PM1_dc`

## set\_aocv\_stage\_weight

```
set_aocv_stage_weight
[-help]
stage_weight
port_list
[-early]
[-late]
[-input]
[-output]
```

While performing advanced on-chip variation (AOCV) analysis of a block in standalone mode, the command allows you to specify the stage weight seen at the port(s) when it is modeled as part of the top level design. The applied stage weights affect the internal weight count of the block for the IO paths. The stage weights can be applied only on ports.

You can view stage weights in the `report_timing` output under the `Stage Weighting` column.

The `set_aocv_stage_weight` command can be used in multi-mode multi-corner mode. The command can be used as part of SDC file.

### Parameters

|                           |                                                                  |
|---------------------------|------------------------------------------------------------------|
| <code>-help</code>        | Prints out the command usage.                                    |
| <code>-early</code>       | Specifies weight for early paths.                                |
| <code>-input</code>       | Specifies input weight for the ports.                            |
| <code>-late</code>        | Specifies weight for late paths.                                 |
| <code>-output</code>      | Specifies output weight for port.                                |
| <code>port_list</code>    | Specifies a list or collection of input, output, and bidi ports. |
| <code>stage_weight</code> | Specifies value of stage weight.                                 |

### Examples

- The following example specifies the stage weight value as 25.5 for port `out0`:

```
tempus > set_aocv_stage_weight 25.5 out0
```

## Related Commands

- `reset_aocv_stage_weight`
- `report_timing`

## set\_aocv\_thresholds

```
set_aocv_thresholds
[-help]
[-min_stage_count_setup <int>]
[-min_stage_count_hold <int>]
[-reset]
[-slack_pruning_threshold <float>]
-view <list_of_views>
```

Limits the minimum AOCV stage depth in graph-based analysis (GBA) mode.

### Parameters

|                                         |                                                                                                                                                                                                       |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                                   | Prints out the command usage                                                                                                                                                                          |
| -min_stage_count_setup<br><int>         | Applies the AOCV stage count floor, during Setup analysis, so that all the instances are guaranteed to have a stage depth no less than the specified value. A value of '0' will remove the assertion. |
| -min_stage_count_hold<br><int>          | Applies the AOCV stage count floor, during Hold analysis, so that all the instances are guaranteed to have a stage depth no less than the specified value. A value of '0' will remove the assertion.  |
| -reset                                  | Removes/sets to default all of the AOCV threshold assertions for specified views.                                                                                                                     |
| -<br>slack_pruning_threshold<br><float> | Controls the slack threshold (in two-pass/slack-based AOCV analysis mode), at which paths are removed from consideration for the next phase of AOCV stage counting.                                   |
| -view <list_of_views>                   | Applies the specified thresholds to the list of analysis views.                                                                                                                                       |

# set\_case\_analysis

```
set_case_analysis
[-help]
{0 | 1 | zero | one | rising | falling | rise | fall | non_switching}
pin_or_port_list
```

Sets constant or transitional values to a list of pins or ports for use by the timing engine. The specified constants or transitional values are valid only during timing analysis and do not alter the netlist. If there is a conflict between the specified `set_case_analysis` value and the logical value from the netlist, the value from the `set_case_analysis` is used in timing analysis.

## Parameters

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                          | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>0   1   zero   one</code>             | Specifies a logic value of 0 or 1, which is propagated through combinational logic to disable or enable parts of logic.                                                                                                                                                                                                                                                                                               |
| <code>non_switching</code>                  | <p>Marks the nets that are in a constant, non-transitioning state. This marking can be used when nets are considered static without the additional impact of logic state injection into the analysis, e.g., when modes are merged into a single constraint mode.</p> <p>The <code>report_cell_instance_timing</code> and <code>report_case_analysis</code> command reports show non-switching as constant values.</p> |
| <code>rising   falling   rise   fall</code> | Specifies a valid transition value to be considered by the timing engine. For example, if a rising value is specified at a certain pin or port, only the rising signal transition from the pin or port is considered for timing analysis and the opposite transition type (falling) is ignored.                                                                                                                       |
| <code>pin_or_port_list</code>               | Specifies a list of ports or pins on which to apply the constant or transitional value. Specify multiple pins by enclosing them with curly braces {} and separating the pin names with white space. The <code>pin_or_port_list</code> argument can be a collection.                                                                                                                                                   |

## Examples

- The following command sets the value of pin i4/A to 1 for use by the timing engine:

```
tempus > set_case_analysis 1 i4/A
```

- The following example shows that the pins P1/P2/B and P1/P3/CI are considered only for a rising transition. The falling transition on these pins is ignored:

```
tempus > set_case_analysis rising {P1/P2/B P1/P3/CI}
```

## Related Commands

- `check_timing -type constant_collision`
- `report_case_analysis`
- `report_timing`
- `set_disable_timing`
- `set_false_path`

## set\_clock\_exclusivity

```
set_clock_exclusivity
[-help]
pin_name
[-exclude_opposite_polarity]
[-exclude_related_input_pins]
[-exclude_same_polarity]
[-group clock_list]
[-inputs string]
```

Controls filtering of mutually-exclusive clocks at strategic points in the design, e.g., the output of clock multiplexers.

### Parameters

|                             |                                                                                                                                                                                                                            |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                       | Prints out the command usage.                                                                                                                                                                                              |
| -exclude_opposite_polarity  | Isolates positive and negative phases of the clocks in the same group. By default, the positive and negative phases of the clocks in the same group that arrive at a strategic point will not be isolated from each other. |
| -exclude_related_input_pins | Allows comparison of clocks going through the same input pins of the specified gate.                                                                                                                                       |
| -exclude_same_polarity      | Allows comparison of clocks going through the same launch or capture paths.                                                                                                                                                |
| -group <i>clock_list</i>    | Defines a set of clocks that are exclusive to the clocks defined in all other groups.                                                                                                                                      |
| -inputs <i>string</i>       | Specifies a list or collection of input pins for which clock exclusivity is to be recognized.                                                                                                                              |
| <i>pin_name</i>             | Specifies the name of the pin.                                                                                                                                                                                             |

## Examples

- The following command will cause downstream analysis from the mux to isolate interactions between the groups:

```
tempus > set_clock_exclusivity -group {CLK1 CLK2} -group {CLK3 CLK4} U1/Y
```

This assertion will cause downstream analysis from pin U1/Y to isolate interactions between the groups. The groups {CLK1 CLK2} and {CLK3 CLK4} are allowed, but all other combinations are considered logically exclusive.

## Related Commands

- `create_clock`

# set\_clock\_gating\_check

```
set_clock_gating_check
[-help]
[object_list]
[-fall]
[-hold hold_value]
[-rise]
[-setup setup_value]
[-high | -low]
```

Specifies or overrides the default setup and hold values for clock gating checks.

## Parameters

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                 | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| -high   -low          | Specifies that the non-controlling value of the clock is high or low. Timing analysis performs the check on the non-controlling value of the clock. By default, the software determines the non-controlling value of the clock using information from the gate's logic. For example, for OR gates the non-controlling value is low. For complex gates, such as XOR and MUX, the clock is never controlling and it does not perform checks unless you specify either the <code>-high</code> option or the <code>-low</code> option. The specified value takes precedence over the default values. This option can only be used with pins or instances.<br><br><b>Note:</b> The clock pin value is controlling if it causes the gate output to be a constant (0 or 1). |
| -hold<br>hold_value   | Specifies the hold value. The default is 0.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| obj_list              | Specifies a list of clocks, instances, or pins. If a clock is specified, the check applies to all the clock gating gates driven by this clock. If an instance is specified, the check applies to all input pins of the instance. If the <code>obj_list</code> argument is not specified, the clock gating check is applied to the current design.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -rise   -fall         | Applies the specified setup (or hold) value to the rising (or falling) signals on the specified pins. If the clock is specified or the <code>obj_list</code> variable is not specified, the value applies to rising or falling, setup or hold. If neither option is specified, the default is both rising and falling.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -setup<br>setup_value | Specifies the setup value. The default is 0.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Note:** The clock gating constraint is not propagated along the clock tree.

The setup check is performed with respect to the edge of the clock signal that changes the state of the clock pin from controlling to non-controlling. For example, for AND and NAND gates, the setup check is performed with respect to the rising edge of the clock input. For OR and NOR gates, the setup check is performed with respect to falling edge of the clock input.

The hold check is performed with respect to the edge of the clock signal that changes the state of the clock pin from non-controlling to controlling. For example, for AND and NAND gates, the hold check is performed with respect to the falling edge of the clock input. For OR and NOR gates, the hold check is performed with respect to rising edge of the clock input.

If the gate logic is unknown, setup and hold checks are performed with respect to both the rising edge and the falling edge of the clock signal and the timing analyzer uses the worst case values.

## Priority Rules for Determining Setup or Hold Values

Timing analysis uses the following priority rules to determine the setup (or hold) value to use for a particular clock gating check:

1. Use the clock gating check assertion on the data pin if it exists
2. Otherwise, use the clock gating check assertion on the clock pin if it exists
3. Otherwise, use the clock gating check assertion on the clock waveform for the clock pin if it exists
4. Otherwise, use the attribute clock gating check assertion if it exists
5. If no clock gating check assertion is present, use the default setup (or hold) value of 0.0.

These rules are demonstrated in the examples below.

**Note:** This command has no effect on a clock gating check defined as a non-sequential setup or hold check in the library and reported as `ClockGatingSetup` or `ClockGatingHold`.

## Examples

Here are some examples.

- The following example shows the priority rules for multiple clock gating check constraints for the gated clock shown in figure below:

### Gated Clock

## Tcl Script for set\_clock\_gating\_check

```
tempus > create_clock -name CLK1 -period 12 -waveform {0 6} clk
...
clock-gating timing check assertions:
On ideal clock waveform
set_clock_gating_check -setup 0.44 [get_clocks {CLK1}]
On clock pin
set_clock_gating_check -hold 0.11 [get_pins {g1/A}]
On data pin
set_clock_gating_check -setup 0.66 -rise [get_pins {g1/B}]
set_clock_gating_check -hold 0.22 -fall [get_pins {g1/B}]
```

Given the previous constraints, the following timing margins are used for slack calculation:

- SETUP g1/B rise: 0.66 -- from assertion on data pin g1/B ([rule 1](#))
- SETUP g1/B fall: 0.44 -- from assertion on ideal clock CLK1 ([rule 3](#))
- HOLD g1/B rise: 0.11 -- from assertion on clock pin g1/A ([rule 2](#))
- HOLD g1/B fall: 0.22 -- from assertion on data pin g1/B ([rule 1](#))

## set\_clock\_groups

```
set_clock_groups
[-help]
[-name name]
[-comment string]
[-logically_exclusive] | [-physically_exclusive] | [[-asynchronous]
[-allow_paths]]
[-group clock_list]
```

Defines clock groups with specified clock definitions. The software assigns all clocks that are defined after you use the `set_clock_groups` command to a default clock group. The software does not apply clock groupings on a master clock to the generated child clocks.

To report the defined clock groups, you can use the following command:

```
report_clocks -groups <name>
```

If there is an overlap in the clock group specification, the software uses the following precedence to resolve the behavior:

1. Physically exclusive
2. Asynchronous
3. Logically exclusive

The software drops any explicit false path assertions between clocks that you have set as either physically or logically exclusive or asynchronous using the `set_clock_groups` command.

An alternative to setting the clocks as physically or logically exclusive using the `set_clock_groups` command is to use the multi-mode mechanism. Generally in an implementation flow, sequential setting of active clocks cannot be used. For concurrent analysis of different modes, you can use an multi-mode based approach to drive IPO instead of using the `set_clock_groups` command.

**Note:** If the `set_clock_groups` constraint is added incrementally in SI mode, an explicit `update_timing -full` command is required (before `report_timing` or `report_constraint`) for SI full accuracy.

### Parameters

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>        | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-allow_paths</code> | Allows paths between asynchronous clock groups to be traced in timing analysis. These paths are blocked by default. When you use this option, the software still considers the paths to be asynchronous for signal integrity considerations. Signal integrity analysis does not support the <code>-allow_paths</code> parameter. Use the <code>-allow_paths</code> parameter with the <code>-asynchronous</code> parameter. |

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-asynchronous</code>              | Defines clock group with asynchronous clocks. Asynchronous clocks have no specified phase relationship. The software considers asynchronous nets to have infinite timing window overlap for signal integrity considerations and considers these as false paths for timing analysis. Use the <code>-allow_paths</code> parameter to trace these paths in timing analysis.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>-comment <i>string</i></code>     | Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-group <i>clock_list</i></code>   | Defines a set of clocks that are exclusive or asynchronous to the clocks defined in all other groups. If you define only one group, then all clocks not in the group implicitly belong to a default clock group. The software automatically adds any new clocks that you define after the <code>set_clock_groups</code> command to this default clock group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-logically_exclusive</code>       | <p>Defines clock group with clocks that do not have any functional paths between them, but coexist in the design at the same time. The software considers aggressor interactions between these clocks for signal integrity considerations, but considers these as false paths for timing analysis.</p> <p><b>Note:</b> The <code>-logically_exclusive</code> parameter does not have any impact on SI analysis.</p> <p>For example, clocks selected via a clock mux select.</p>                                                                                                                                                                                                                                                                                                                                                |
| <code>-name <i>name</i></code>          | Specifies the names of the clock groups to be added.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-<br/>physically_exclusive</code> | <p>Defines clock group with clocks that cannot exist in the design at the same time. The software does not consider aggressor interactions between clock groups that are physically exclusive for signal integrity considerations.</p> <p>From the perspective of SI analysis, all attackers that are physically exclusive with the victim net are ignored for both glitch and noise-on-delay analysis. Attacker nets that belong to physically exclusive groups cannot attack together. In this case, all sets of attackers belonging to all the physically exclusive groups are evaluated and the set of nets that has the highest impact on SI analysis is chosen.</p> <p>For timing analysis, the software considers these clock groups as false paths.</p> <p>Example: multiple clocks defined on the same source pin</p> |

## Examples

Here are some examples.

- The following commands assert two different clocks on the same clock root port, and uses `set_clock_groups` to isolate them from each other:

```
tempus > create_clock -name SYSCLK -period 10 [get_ports sclk]
tempus > create_clock -name SCANCLK -period 100 -add [get_ports sclk]
tempus > set_clock_groups -name PHY_EX_SCLK -physically_exclusive -group {SYSCLK} -group {SCANCLK}
```

- The following command declares a single bus clock to be asynchronous to all of the other on board clocks in the design (which remain in the default clock group):

```
tempus > set_clock_groups -name ASYNCH_BUS -asynchronous -group {BUSCLK}
```

Assume a design with four clocks CLK1, CLK2, CLK3, and CLK4.

- The following command defines CLK1 physically exclusive to CLK2, CLK3 as well as CLK4.  

```
tempus > set_clock_groups -name group1 -group CLK1 -physically_exclusive
```
- The following command defines CLK1 and CLK2 to be physically exclusive to CLK3 and CLK4.  

```
tempus > set_clock_groups -name group2 -group {CLK1 CLK2} -physically_exclusive
```
- The following command defines CLK1 and CLK2 as physically exclusive to CLK3  

```
tempus > set_clock_groups -name group3 -group {CLK1 CLK2} -group {CLK3} -physically_exclusive
```
- The following command defines the following:  

```
tempus > set_clock_groups -name group4 -group {CLK1} -group {CLK2} -group {CLK3} -physically_exclusive
```

  - CLK1 physically exclusive to CLK2 and CLK3.
  - CLK2 physically exclusive to CLK1 and CLK3.
  - CLK3 physically exclusive to CLK1 and CLK2.
- The following example shows that the clock group {clkA clkB} is asynchronous only to clock group {clkC clkD}:

```
tempus > set_clock_groups -asynchronous -group {clkA clkB} -group {clkC clkD}
```

If an extra clock clkE is defined in the design, then timing check will be allowed in between the first group to clkE and second group to clkE.

- In the following example since only one clock group is specified with the command `set_clock_groups` command, so the specified clock group is considered to be asynchronous to all the other clocks in the design:

```
tempus > set_clock_groups -asynchronous -group {clkA clkB}
tempus > set_clock_groups -asynchronous -group {clkC clkD}
```

## Related Commands

- `create_clock`
- `report_clocks`
- `reset_clock_groups`

## set\_clock\_latency

```
set_clock_latency
[-help]
<value>
<obj_list>
[-clock <clock_list>]
[-clock_gate]
[-fall]
[-max]
[-min]
[-rise]
[-source [-early] [-late] [-dynamic <jitter_val>]]
```

Specifies ideal internal clock value and external clock arrival delay.

Clock value has two components:

- Source value:
  - Specified using the `-source` parameter and is the delay from the external clock generator to the clock port of the design.
  - Applied when the clock is either ideal or propagated.
  - `set_clock_latency` set on a clock port has higher precedence than `set_clock_latency` set on a clock waveform.
  - Specified on clock waveforms with both the `set_input_delay` command and the `set_output_delay` command.
- Network value (clock tree delay):
  - Default value type and is the delay from the clock port to the register.
  - Applied only when the clock is ideal. When the clock is propagated, this delay is replaced by the actual clock tree delays.
  - Specified on a clock waveform or a clock port is ignored if the clock is propagated.
  - `set_clock_latency` set on a timing pin has higher precedence than `set_clock_latency` set on a waveform.
  - If there are multiple `set_clock_latency` and `set_propagated_clock` assertions between the clock waveform, clock root and clock endpoint, the closest assertion to the clock endpoint takes precedence.
  - Specified on internal circuit pins or hierarchical ports and used in the fanout cone of the network value pin, when a clock is ideal.

Use the `set_clock_latency` command in two ways:

- To specify clock value for a clock waveform:
  - Use the following syntax for source value associated with a clock signal:  
`set_clock_latency [-source] [-early | -late] [-min ][-max] value obj_list`
  - Use the following syntax for network value associated with a clock signal:  
`set_clock_latency [-min] [-max] value obj_list`

You cannot specify the `-late` and `-early` parameters for network value.

Specifying value on a port or pin overrides any previous value specified on the port pin or waveform. The `obj_list` argument is the list of the clock waveform names as specified by the [create\\_clock](#) command.

- To specify clock value on clock pins:
  - Use the following syntax for source delay on a clock port:  
`set_clock_latency -source [-early | -late] [-rise] [-fall]  
insertion_delay obj_list`
  - Use the following syntax for network delay on a clock pin:  
`set_clock_latency [-min] [- max] [-rise] [-fall]  
insertion_delay -pin obj_list`

When a clock is ideal, the last specification along a path is used. This is useful when you want to intentionally skew the clock tree and model the physical hierarchical clock tree.

## Parameters

|                                      |                                                                                                                                                                                                                                                                                                             |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                   | Prints out the command usage.                                                                                                                                                                                                                                                                               |
| <code>-clock<br/>clock_list</code>   | Associates clock value constraints, placed at the pin level, with a specific clock. This makes it possible to specify a different value per clock.<br><br><b>Note:</b> You cannot use the <code>-clock</code> parameter with clock waveform objects.                                                        |
| <code>-clock_gate</code>             | Allows setting the local clock value on pin or port objects. This setting overwrites the existing value of clock gating cells and is used when performing timing checks against the specified pins or ports.                                                                                                |
| <code>-dynamic<br/>jitter_val</code> | Specifies the portion of source clock latency value that can have cycle-to-cycle variation. When calculating CPPR adjustment this portion is removed from CPPR adjustment for different clock edge checks (e.g., setup), but it remains as part of cppr adjustment for same clock edge checks (e.g., hold). |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-early   -late</code> | <p>Specifies clock arrival time with respect to the early or the late time of the clock signal. In setup analysis, launch path is the late path and capture path is the early path. In hold analysis, launch path is the early path and the capture path is the late path. If neither parameter is specified, the default is both early and late. Use these parameters only with the <code>-source</code> parameter. You cannot use these parameters with network value. Specify the clock value at the given operating corner.</p> <p><b>Note:</b> The <code>-min</code> and <code>-max</code> parameters refer to the operating corner and the <code>-early</code> and <code>-late</code> parameters refer to the clock arrival time at the source. Use the <code>-early</code> and <code>-late</code> parameters with the <code>-source</code> parameter to specify the four different clock latencies.</p> |
| <code>value</code>          | Specifies the value of the latency, in library units, as a floating point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>obj_list</code>       | <p>Specifies a list of clock waveform names or a list of pins to associate with the clock value. The pin can be a port or an instance pin.</p> <p>Setting source value on a pin is ignored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-max</code>           | Specifies the clock value for a particular operating corner. Apply the <code>-max</code> parameter to the maximum operating corner.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-min</code>           | Specifies the clock value for a particular operating corner. Apply the <code>-min</code> parameter to the minimum operating corner.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-rise   -fall</code>  | Specifies the <code>-rise</code> or <code>-fall</code> parameter to the waveform at register clock pins for ideal value and to the waveform at the source for source value. Ideal network value does not change polarity when crossing negative unate arcs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-source</code>        | <p>Specifies the source latency. If you do not use the <code>-source</code> parameter, the network latency will be applied.</p> <p>You can use the <code>timing_generated_clocks_inherit_ideal_latency</code> attribute to include the closest applied network latency for ideal inheritance. However, when the <code>-source</code> parameter is used, the software will completely override any inheritance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Examples

- The following set of commands enable you to create a clock using the `create_clock` command and apply latency to the created clock using the `set_clock_latency` command:

```
tempus > create_clock CLK2 -period 20 [get_ports {clkA clkB clkD}]
tempus > set_clock_latency -source 2 {clkB clkD} # Define port settings
tempus > set_clock_latency -rise 5 {clkB clkD} # Define port settings
tempus > set_clock_latency 3 -early -late -source CLK1 # Define latency and waveform
settings
```

## Related Commands

- `reset_clock_latency`
- `create_clock`
- `set_clock_transition`
- `set_clock_uncertainty`
- `set_input_delay`
- `set_output_delay`
- `set_propagated_clock`

## set\_clock\_sense

```
set_clock_sense
[-help]
[-positive | -negative | -stop_propagation | -logical_stop_propagation | -stoptype_list]
[-clocks clock_list]
pin_or_port_list
```

Defines the phases of a clock or clock source that can propagate beyond a port or instance pin. The clocks can be selectively or entirely blocked through the pin to all downstream logic. Additionally, data relating to clocks can be blocked through the pin.

**Note:** The `set_clock_sense` command is now obsolete. This command will continue to be supported in the current release, but will be removed in the next major release of the software.

### Parameters

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                     | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-clocks <i>clock_list</i></code> | Specifies a list of clocks passing through a specified point to which the constraint applies.<br><br>When this parameter is not specified, the filtering of clock phase will be applicable to all the clocks passing through that specified point.<br><br>This parameter must be used with a specified pin name and one of the parameters : <code>-positive</code> , <code>-negative</code> , <code>-stop_propagation</code> , <code>-logical_stop_propagation</code> , <b>or</b> <code>-stop</code> . |
| <code>-logical_stop_propagation</code> | Stops the propagation of specified clocks passing through the specified pins.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-negative</code>                 | Specifies that positive phase filtered clocks pass through pins in the <i>pin_list</i> .                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>pin_or_port_list</i>                | Specifies the list or collection of cell output pins. The unateness specified by the <code>set_clock_sense</code> command is applied to clocks propagating through the specified point.                                                                                                                                                                                                                                                                                                                |
| <code>-positive</code>                 | Specifies that negative phase filtered clocks pass through pins in the <i>pin_list</i> .                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-stop_propagation</code>         | Stops the propagation of specified clocks and clock source data paths passing through the specified pins.                                                                                                                                                                                                                                                                                                                                                                                              |

`-stop type_list`

Applies clock sense to object types specified in the *type\_list*. The type list options are - all, clock, data, clock\_source\_data, default\_data.

These are explained below:

- **all:** Stops all phases from propagating. This is equivalent to specifying both the `clock` and `data` options.
- **clock:** Stops clock phases launched by clock(s) specified in the *clock\_list* from propagating, and is equivalent to existing - `logical_stop_propagation`.
- **data:** Stops all data phases launched by clock(s) specified in *clock\_list*, starting from the pins/ports specified in *pin\_or\_port\_list*. The objects in the *pin\_or\_port\_list* can be selected anywhere in the design - clock/data network.
- **clock\_source\_data:** Stops only clock source data phases from propagating. The combination of `clock_source_data` and `clock` is equivalent to the existing `-stop_propagation` option.
- **default\_data:** Stops only default data phases (representing constrained paths) from propagation. This option cannot be specified along with the `-clock clock_list`.

The `-stop` parameter extends the capability of the `set_clocks_sense` command to selectively block data timing phases. This parameter provides a more generalized use model for selecting among all types of paths that should be filtered.

The `-stop` parameter is mutually exclusive with the `-positive`, `-negative`, `-stop_propagation`, and `-logical_stop_propagation` options.

## Examples

- The following command stops the propagation of clock CLK1 through the pin CLKBUF1/Z:  

```
tempus > set_clock_sense -logical_stop_propagation -clocks CLK1 CLKBUF1/Z
```
- The following command allows the positive phase clock CLK1 to pass through CLKBUF1/Z but filters out the negative phase clock CLK1:  

```
tempus > set_clock_sense -positive -clocks CLK1 CLKBUF1/Z
```
- The following command stops clock phases starting from pin1:  

```
tempus > set_clock_sense pin1 -stop {clock}
```

or

```
tempus > set_clock_sense pin1 -logical_stop_propagation
```
- The following command stops data phases based only on CK1 and CK2 starting from pin1:  

```
tempus > set_clock_sense pin1 -stop {data} -clocks {CK1 CK2}
```
- The following command stops only the clock source data phases starting from pin1:  

```
tempus > set_clock_sense pin1 -stop {clock_source_data}
```
- The following command stops the clock and clock source data from pin1:  

```
tempus > set_clock_sense pin1 -stop {clock clock_source_data}
```

or

```
tempus > set_clock_sense pin1 -stop_propagation
```

## Related Commands

- [reset\\_clock\\_sense](#)

# set\_clock\_transition

```
set_clock_transition
[-help]
[-rise]
[-fall]
[-min]
[-max]
[-min | -max]
transition_time
clock_list
```

Specifies the transition time of sequential endpoints of the ideal clock network.

This command only affects ideal clock networks, so typically it is used before the clock network is implemented. If no clock transition is explicitly specified for an ideal clock, the system's default transition time (often close to 0.0) is used. For propagated clocks, the calculated transition times are used, so you can set propagated clocks only after the final clock tree is constructed.

This command only affects sequential clock endpoints, typically the clock pin of registers in the combinational fanout of the clock. Any data endpoints that are also in the combinational fanout of the clock will not be affected. The software will always use the propagated transition times. You can consider turning off clock-source data paths until the clock tree is built or, you can use the [set\\_ideal\\_network](#) command for additional control.

## Parameters

|                              |                                                                                                                                                                                                                                                                                                                  |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>           | Prints out the command usage.                                                                                                                                                                                                                                                                                    |
| <code>clock_list</code>      | Specifies a list of clocks only with ideal mode in the design, which affects the slew times on all register clock pins in the transitive fanout of the specified clocks. Specified <code>set_clock_transition</code> values on register clock pins in the fanout of a clock with propagated latency are ignored. |
| <code>-rise   -fall</code>   | Specifies the rising or falling edge of the register clock pins on which the slew time is asserted.                                                                                                                                                                                                              |
| <code>-min   -max</code>     | Specifies the clock slew time for minimum or maximum process corner slew time.                                                                                                                                                                                                                                   |
| <code>transition_time</code> | Specifies the slew time (transition time) of the clock pins.                                                                                                                                                                                                                                                     |

## Examples

- The following commands specify a 2.0 rise slew time and a 1.0 fall slew time for register clock pins clocked by `CLKA`:

```
tempus > set_clock_transition -rise 2.0 [get_clocks CLKA]
```

```
tempus > set_clock_transition -fall 1.0 [get_clocks CLKA]
```

## Related Commands

- `set_clock_latency`
- `set_clock_uncertainty`
- `set_input_delay`
- `set_propagated_clock`

# set\_clock\_uncertainty

```
set_clock_uncertainty
[-help]
uncertainty_value
[-setup]
[-hold]
[-half_cycle_jitter | -full_cycle_jitter]
[-rise | -fall]
{ {-from | -rise_from | -fall_from} clksig_from_list
 {-to | -rise_to | -fall_to} clksig_to_list
 | clock_or_clock_pin
}
```

Specifies the clock uncertainty (skew) on the clock network.

If you set multiple constraints with the `set_clock_uncertainty` command, the constraints set with the `-from* clksig_from_list/-to* clksig_to_list` parameters take precedence over simple constraints set on clock objects.

Clock uncertainty set on pins takes highest precedence and overrides clock based uncertainty.

The `set_clock_uncertainty` command can also support clock uncertainty for period, pulse width, skew, and separation checks. To enable this feature, you need to set `timing_enable_uncertainty_for_clock_checks` attribute to `true`. By default, the attribute is set to `false`. For more details, see [timing Category Attributes](#).

## Parameters

|                                                                               |                                                                                                                                                                                                                                                                                                                      |

You also can specify a collection of clocks, or clock root pins or ports.</p> <p><b>Note:</b> You cannot use this parameter when any of the <code>-from</code> and <code>-to</code> parameter pairs are specified.</p> |
| <code>-rise   -fall</code>                                                    | <p>Specifies the rising or falling edge at the capture clock pin on which the uncertainty is applied.</p> <p><i>Default:</i> Applies uncertainty on both edges</p> <p><b>Note:</b> You must use these parameters with the <code>-to</code> and <code>-from</code> parameters.</p>                                                                                                                                                                                                                                                         |
| <code>-setup/-hold</code>                                                     | <p>Specifies whether the clock uncertainty applies to setup or hold checks.</p> <p><i>Default:</i> Applies to both setup and hold check</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-to   -rise_to   -<br/>fall_to<br/>clk_sig_to_list</code>               | <p>Applies the uncertainty value to the specified list of capture clocks.</p> <p><b>Note:</b> You must specify one of these parameters with one of the <code>-from</code>, <code>-rise_from</code>, or <code>-fall_from</code> parameters. You cannot use these parameters if <code>clock_or_clock_pin</code> is specified.</p>                                                                                                                                                                                                           |
|                                                                               | <ul style="list-style-type: none"> <li>• <b>-fall_to:</b> Applies the uncertainty value only to the falling edge of the capture clocks.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                        |
|                                                                               | <ul style="list-style-type: none"> <li>• <b>-rise_to:</b> Applies the uncertainty value only to the rising edge of the capture clocks.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                         |
|                                                                               | <ul style="list-style-type: none"> <li>• <b>-to:</b> Applies the uncertainty value to both the rising and falling edges of the capture clocks.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                 |

## Examples

- The following command gives all paths starting from registers clocked by `clk1` to registers clocked by the rising edge of `clk2` a hold uncertainty of 2.0:

```
tempus > set_clock_uncertainty 2.0 -from clk1 -to clk2 -rise -hold
```

In case of multiple constraints, the actual uncertainty applied by the software depends on which constraint matches the specific path in question.

- The following command sets an uncertainty on the `clk_in` clock root pin that is applied to all the register pins in the fanout of `clk_in`:

```
tempus > set_clock_uncertainty 1.2 clk_in
```

- The following command specifies an inter-clock uncertainty of 0.2 between clock waveforms `clk1` and `clk2`:

```
tempus > set_clock_uncertainty 0.2 -from clk1 -to clk2
```

- The following command specifies a target uncertainty of 0.5 for all registers clocked by the clock waveform `ideal_clk1`:

```
tempus > set_clock_uncertainty 0.5 ideal_clk1
```

## Related Commands

- `report_clocks`
- `set_clock_latency`
- `set_clock_transition`

# set\_data\_check

```
set_data_check
[-help]
<check_value>
[-clock <clock_object>]
[-hold]
[-setup]
{-from <pin_or_port_list> | -rise_from <pin_or_port_list> | -fall_from <pin_or_port_list>}
{-to <pin_or_port_list> | -rise_to <pin_or_port_list> | -fall_to <pin_or_port_list>}
```

Sets data-to-data checks using the specified values of setup and hold time. Data-to data checks are non-sequential checks that constrain a data signal with respect to another data signal. The reference (related) delay is defined by the `-from` pin/port and the target(s) by the `-to` pin/port. Note that these need not to be on the same component.

In a normal sequential check, a data signal is constrained with respect to a clock signal. In a sequential setup, the clock is incremented by a cycle between launch (`-from`) and capture (`-to`). In contrast, a data-to-data setup check is performed on the same edge as the launch. A clock can be specified to refine the triggering condition of the reference signal. You can use the `set_multicycle_path` constraint to adjust the cycle accounting rules.

## Parameters

|                            |                                                                                                                                                                                                                                                                                                                                                                                             |

## Examples

- The following example demonstrates how the `set_data_check` command can be used to constrain signals:

Consider two control signals, say XE and SE, going to a macro block. Both of these are derived from the same state machine, and hence launched from the same clock domain. You want XE to reach the macro earlier than SE. The `set_data_check` constraint can meet this design intent, by applying data checks on non-sequential signals, without setting path specific limits using the following command:

```
tempus > set_data_check -from [get_pins {sub/SE}] -to [get_pins {sub/XE}] -setup 0.5
```

The `set_data_check` command establishes data-to-data checks using similar ideas of setup and hold time as in sequential checks, with the `-from` parameter denoting the reference signal (the clock in a traditional setup/hold timing check), and the `-to` parameter indicating the signal being constrained.

## Related Commands

- `reset_data_check`

# set\_disable\_clock\_gating\_check

```
set_disable_clock_gating_check
[-help]
pin_or_inst_list
```

Disables clock gating checks for the specified instances or pins.

The `set_disable_clock_gating_check` command has a character limit for the details that are logged into the SDC file (the `write_sdc` command output). This helps to prevent SDC file errors.

## Parameters

|                         |                                                                  |
|-------------------------|------------------------------------------------------------------|
| <code>-help</code>      | Prints out the command usage.                                    |
| <i>pin_or_inst_list</i> | Specifies the list of pins or instances that are to be disabled. |

## Examples

- The following command disables clock gating checks for the specified instance:

```
tempus > set_disable_clock_gating_check [get_cells clockgate1]
```

## Related Commands

- `reset_disable_clock_gating_check`

## set\_disable\_timing

```
set_disable_timing
[-help]
[-from pin_name -to pin_name]
obj_list
```

Disables timing propagation through the specified arcs, or a collection of instance-specific arcs that are created using the `get_arcs` command.

### Parameters

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                                              | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -from<br><i>pin_name</i><br>-to<br><i>pin_name</i> | <p>Specifies the arc that is to be disabled. Specify the <code>-from</code> and <code>-to</code> options together.</p> <p>You can specify the <code>-from</code> and <code>-to</code> parameters when the <i>obj_list</i> contains instance or library cell objects. Do not specify the <code>-from</code> and <code>-to</code> parameters when the <i>obj_list</i> includes instance pin or library cell pin objects.</p> <p>The <code>-from</code> and <code>-to</code> options are optional. If not specified, all cell arcs found in the instance or library cell objects are disabled.</p> |
| <i>obj_list</i>                                    | <p>Specifies the instance, instance pin, library cell, library cell pin objects, collection of library arcs, or collection of timing arcs.</p> <p>If the <i>obj_list</i> includes instance pin or library cell pin objects, all cell arcs attached to the specified pin objects are disabled.</p> <p>If the <i>obj_list</i> contains instance or library cell objects, and the <code>-from</code> and <code>-to</code> parameters are not specified, all arcs found in the specified instance or library cell objects are disabled.</p>                                                         |

### Examples

Here are some examples.

- The following command disables the arcs that lead to the output pins of the `i1`, `i2`, and `i3` instances. Note that timing checks at the inputs of `i1`, `i2`, and `i3` are still active.  

```
tempus > set_disable_timing [get_cells {i1 i2 i3}]
```
- The following command disables the arc from pin `B` to pin `Z` in the `i1` and `i2` instances, and the arc from pin `A` to pin `Z` in the `i3` instance:

```
tempus > set_disable_timing -from B -to Z [get_cells {i1 i2}]
tempus > set_disable_timing -from A -to Z [get_cells {i3}]
```

- The following example disables timing check arcs from pin `CLK` to pin `D` of the `ff1` instance:

```
tempus > set_disable_timing -from CLK -to D [get_cells ff1]
```

- The following example disables the outgoing cell arcs from instance input pin `i1/B`:

```
tempus > set_disable_timing [get_pins i1/B]
```

- The following example disables all arcs found in any instances whose reference cell is `AN2`:

```
tempus > set_disable_timing [get_lib_cells AN2]
```

- The following example disables a collection of timing arcs:

```
tempus > set arcs [get_lib_arcs -from typical/MX2X1/S0 -to typical/MX2X1/Y]
tempus > set_disable_timing [index_collection $arcs 3]
```

- The following example disables arcs created using `filter_collection` on library timing arcs:

```
tempus > set arc [filter_collection $arcs {when == "(A)&(!B)"}]
tempus > set_disable_timing $arc
```

## Related Commands

- [report\\_timing](#)
- [reset\\_disable\\_timing](#)

# set\_dont\_touch

```
set_dont_touch
[-help]
obj_list
[{true | false}]
```

Prevents the specified object from being modified during optimization. However, the specified object can be moved during optimization.

When the `set_dont_touch` command is set to `true`, the specified nets cannot be buffered or become part of the logic cone restructuring. However, you can resize the instances connected to this net because the `set_dont_touch` attribute does not affect the connected instances.

## Parameters

|                             |                                                                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>          | Prints out the command usage.                                                                                                     |
| <code>{true   false}</code> | Sets or removes the <code>set_dont_touch</code> attribute for the specified list of objects.<br><i>Default:</i> <code>true</code> |
| <code>obj_list</code>       | Specifies the collection or list of instances, library cells, nets, or sub-modules.                                               |

## Examples

- The following command prevents the specified instance from being modified:  

```
tempus > set_dont_touch [get_cells {TWA/FF1}]
```
- The following commands prevent the specified net from being modified and check the setting with `get_property`:  

```
tempus > set_dont_touch clk1_net
tempus > get_property [get_nets clk1_net] dont_touch true
```
- The following commands can be used to prevent any ECO inside `RESULTS_CONV_INST` hierarchical instance:  

```
tempus > set_dont_touch [get_cells RESULTS_CONV_INST/*] true
tempus > set_dont_touch [get_nets RESULTS_CONV_INST/*] true
```

The `set_dont_touch RESULTS_CONV_INST/* true` command will return `[get_cells RESULTS_CONV_INST/*]` only. This is because the software looks into the first match (type of object). If a match is not found, then the successive objects are searched.

## Related Commands

- `get_cells`
- `get_lib_cells`
- `get_nets`
- `get_property`

# set\_dont\_touch\_network

```
set_dont_touch_network
[-help]
obj_list
[-no_propagate]
```

Prevents the combinational path connected to the given clocks, pins, or ports from being modified.

## Parameters

|                            |                                                                                                                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>         | Prints out the command usage.                                                                                                                                                                                             |
| <code>-no_propagate</code> | Preserves all the nets driven by the specified pin up to the first leaf-cell input (combinational or sequential).<br><br>If this parameter is omitted, then preserving stops at the first sequential cell in the network. |
| <i>obj_list</i>            | Specifies the objects - clocks, pins, or ports - to be preserved.                                                                                                                                                         |

## Examples

- The following command prevents the combinational path connected to the specified pin from being modified:

```
set_dont_touch_network [get_pins and1/z]
```

## Related Commands

- `get_pins`

## set\_dont\_use

```
set_dont_use
[-help]
lib_cell_list
[true | false]
```

Prevents the specified design, hierarchical module, or library cells from being used during optimization. However, optimization is allowed to size out don't use cells if instances are already there in the initial netlist.

### Parameters

|                            |                                                                                                                      |
|----------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>         | Prints out the command usage.                                                                                        |
| <code>lib_cell_list</code> | Specifies the list of library cells.                                                                                 |
| <code>true   false</code>  | Sets or removes the <code>set_dont_use</code> attribute for the specified object list.<br>Default: <code>true</code> |

### Examples

- The following command resets all the previously defined `clock_sense` constraints from a design:  

```
tempus > reset_clock_sense -all
```

### Related Commands

- `set_clock_sense`

## set\_drive

```
set_drive
[-help]
[-rise] [-fall]
[-max] [-min]
resistance_value
port_list
```

Sets the drive resistance on the specified input and/or bidirectional ports of the top cell.

The drive resistance models the cell driving the port. This resistance is used to compute the load dependent delay and the slew at the specified ports. The load-dependent delay is added to the arrival times.

The load-dependent delay and the slew are computed by multiplying the drive resistance by the wire capacitance of the net connected to the port.

Use the [report\\_ports](#) command to view drive resistances asserted on ports.

### Parameters

|                               |                                                                                                                                                                                                                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>            | Prints out the command usage.                                                                                                                                                                                                                                                              |
| <code>-fall</code>            | Specifies that the drive resistance is to be used for the falling transition at the specified ports. By default, if neither the <code>-rise</code> nor the <code>-fall</code> option are specified, the drive resistance applies to both the rising transition and the falling transition. |
| <code>-min</code>             | Specifies that the drive resistance is to be used to compute the early path delay. By default, if neither the <code>-min</code> option nor the <code>-max</code> option is specified, the drive resistance applies to both the early path delay and the late path delay.                   |
| <code>-max</code>             | Specifies that the drive resistance is to be used to compute the late path delay. By default, if neither the <code>-min</code> option nor the <code>-max</code> option is specified, the drive resistance applies to both the early path delay and the late path delay.                    |
| <code>port_list</code>        | Specifies a list of input or bidirectional ports on which the drive resistance is set.                                                                                                                                                                                                     |
| <code>resistance_value</code> | Specifies the value of the drive resistance. This value must be greater than or equal to zero. The drive resistance is in units found in the target technology library.                                                                                                                    |

|                    |                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-rise</code> | Specifies that the drive resistance is to be used for the rising transitions at the specified ports. By default, if neither the <code>-rise</code> option nor the <code>-fall</code> option are specified, the drive resistance applies to both the rising transition and the falling transition. |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

- The following command sets a drive resistance of 2.0 for the early path, the late path, the rising and the falling transitions at the in1 and in2 ports and shows how drive resistances are reported using the `report_ports` command as shown in the example below:

```
tempus > set_drive 2.0 [get_ports {in1 in2}]
tempus > report_ports -type drive_resistance -pin [get_ports {in1 in2}]
```

The following report is displayed:

```

Early Late

Pin Dir Assertion Clock Rise Fall Rise Fall
Name

in1 IN drive_resistance * (D) (P) 2.000 2.000 2.000 2.000
in2 IN drive_resistance * (D) (P) 2.000 2.000 2.000 2.000

```

## set\_driving\_cell

```
set_driving_cell
[-help]
[-library library_name]
-lib_cell cell_name
[-pin pin_name]
[-from_pin from_pin_name]
[-rise]
[-fall]
[-min]
[-max]
[-multiply_by factor]
[-no_design_rule]
[-input_transition_rise rise_slew_value]
[-input_transition_fall fall_slew_value]
port_list
```

Models the drive capability of an external driver connected to the input port. Use this command only for timing analysis. The command does not affect the electrical properties of the design, which means that the capacitance of the output pin of the driving cell does not add to the total capacitance of the input port.

To model the drive capability of the external driver, the timing analyzer computes an offset to the arrival time of an input, and changes the slew time used to compute the delay for the next cell. The timing analyzer computes the offset by subtracting the zero load delay from the total delay of the cell. The `set_driving_cell` command uses the offset value to identify a cell from the library to drive the specified input port(s).

This command overrides the `set_drive` command per port or per net, if it is the last command applied. Also, if the `set_driving_cell` command is set for a port, the `set_input_transition` command is ignored for that port. If you do not define drive using the `set_driving_cell` command, the software uses the default value defined in the configuration file. The default value is 0.1ps.

### Parameters

|       |                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------|
| -help | Prints out the command usage.                                                                     |
| -fall | Annotates only the falling drive assertion. The default is to annotate both rise and fall delays. |

|                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <code>-from_pin</code><br><code>from_pin_name</code>                | <p>Specifies the name of the input port of the driver cell that has an arc to the output port of the driver cell, which is connected to the input port of the design. This option is required only if there are multiple timing arcs in the driver cell from its input ports to its output ports, and the arcs from those pins have different drive characteristics.</p> <p>If you do not specify the <code>-from_pin</code> option, the default is to use the first timing arc found on the library cell.</p> |
| <code>-input_transition_fall</code><br><code>fall_slew_value</code> | Specifies the slew value for the falling signal at the input of the drive cell.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-input_transition_rise</code><br><code>rise_slew_value</code> | Specifies the slew value for the rising signal at the input of the drive cell.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-lib_cell cell_name</code>                                    | Specifies the name of the driver cell. This parameter supports wildcard patterns and collections.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-library library_name</code>                                  | Specifies the name of the library that contains the driving cell.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-max</code>                                                   | Annotates only the late drive assertion. The default is to annotate both early and late.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>-min</code>                                                   | Annotates only the early drive assertion. The default is to annotate both early and late.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-multiply_by factor</code>                                    | Specifies a multiplier for the drive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-no_design_rule</code>                                        | <p>Does not allow transfer of design rules from the driving cell to the port.</p> <p>If you do not specify this option, the design rules (such as <code>max_capacitance</code>) of the library pin are applied to the port.</p>                                                                                                                                                                                                                                                                                |
| <code>-pin pin_name</code>                                          | Specifies the name of the output port of the driver cell that drives the signal at the input port of the design. This option is required if there are multiple output ports on the driver. If there is only one output port on the driver cell, then using this option is not necessary.                                                                                                                                                                                                                       |
| <code>port_list</code>                                              | Specifies the list of ports driven by the driver cell.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-rise</code>                                                  | Specifies only the rising drive assertion is annotated. The default is to annotate both rise and fall delays.                                                                                                                                                                                                                                                                                                                                                                                                  |

## Examples

- The following command sets 'AND' cell (arc B -> Y) as the driving cell for the input port IN1:

```
tempus > set_driving_cell -lib_cell AND -from_pin B -pin Y IN1
```

## Related Commands

- `reset_driving_cell`
- `all_inputs`
- `report_ports`
- `set_drive`
- `set_input_transition`

## set\_false\_path

```
set_false_path
[-help]
[-hold | -setup]
[-rise]
[-fall]
[[-from | -rise_from | -fall_from} from_list]
[[-through | -rise_through | -fall_through} through_list]
[[-to | -rise_to | -fall_to} to_list]]
```

Identifies false paths in a design, and breaks or disables specific instance timing arcs in a design.

 To break combinational loops, use the `set_disable_timing` command instead of the `set_false_path` command.

The `set_false_path` command differs from the `set_disable_timing` command as follows:

- `set_false_path` command selectively disables the arrival time information depending on the precedence rules.
- `set_false_path` command does not affect constant values.
- `set_disable_timing` command physically snips a timing arc such that neither arrival times nor constant values propagate through it.
- `set_disable_timing` command is applied in all cases to valid timing arcs.

The `set_false_path -from fpin` command disables all timing paths whose source pin is an `fpin`. Similarly, the `set_false_path -to tpin` command disables all timing paths whose sink pin is a `tpin`. Using the `set_false_path -from fpin -to tpin` command disables all timing paths whose source is `fpin` and sink is `tpin`.

Specify a group of pins by enclosing the group with curly braces (`{}`) within one `set_false_path` command.

 To set a false path for any path beginning at `p1` or `p2` and terminating at `t1` or `t2`, group the pins as follows:  
`set_false_path -from {p1 p2} -to {t1 t2}`

**Note:** This method of pin grouping reduces the number of exceptions. Having large numbers of

exceptions adversely impacts the run time of the timing analysis commands.

## Parameters

|                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

If a clock is specified as the -to object, all primary outputs and registers clocked by that clock are used as endpoint.</p> <p>By default, the -to option applies the constraint to both the rising and the falling edges.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                                 | <p><b>-rise_to:</b> Applies the false path constraint at the rising edge of the signal on the to pins.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                                 | <p><b>-fall_to:</b> Applies the false path constraint at the falling edge of the signal on the to pins.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Examples

- The following command disables hold checking from `ff1` to `ff2`:  

```
tempus > set_false_path -hold -from ff1 -to ff2
```
- The following command sets all timing paths from `ff1/CK` to `D` input of `ff2` that pass through `u1/Y` and one or more of `u2/Y` and `u3/Y` as false paths:  

```
tempus > set_false_path -from ff1/CK -through {u1/Y} -through {u2/Y u3/Y} -to ff2/D
```
- The following command sets all timing paths from the rise of `ff1/CK` to `ff2/D` through one or more of `u1/Y` and `u4/Y` as false paths:  

```
tempus > set_false_path -rise_from ff1/CK -through {u1/Y u4/Y} -to ff2/D
```

## set\_fanout\_load

```
set_fanout_load
[-help]
value
port_list
```

Specifies the fanout load on a set of ports.

The library instance pins can have fanout loads defined in the technology library. The fanout does not have specific units so it is assumed that a fanout as used by the constraints is consistent with the fanout defined in the technology libraries. If a pin or port has no fanout attribute, either from the constraints or from the technology library, then the fanout load will be zero. The fanout load is used only for design rule checking and does not impact the timing results.

### Parameters

|                        |                                                                   |
|------------------------|-------------------------------------------------------------------|
| <code>-help</code>     | Prints out the command usage.                                     |
| <code>value</code>     | Specifies the fanout load value for the port or ports.            |
| <code>port_list</code> | Specifies the list of ports for which the fanout load is applied. |

### Examples

- The following command sets the fanout load of port `out` to 2:  

```
tempus > set_fanout_load 2 out
```
- The following command sets the fanout load of ports `in1` and `in2` to 1:  

```
tempus > set_fanout_load 1 {in1 in2}
```
- The following command sets the fanout load of element 3 of port `out` to 12:  

```
tempus > set_fanout_load 12 { out[3] }
```
- The following command sets the fanout load of all the ports to 2:  

```
tempus > set_fanout_load 2 [get_ports *]
```

## set\_ideal\_latency

```
set_ideal_latency
[-help]
[-min]
[-max]
[-rise]
[-fall]
value
pin_or_port_list
```

Specifies the ideal latency to use for input or output leaf-cell pins and top-level ports that are part of an ideal network. These set a point delay on the specified object.

**Note:** You should specify `set_ideal_latency` with `set_ideal_network` to view the ideal latency result.

### Parameters

|                               |                                                       |
|-------------------------------|-------------------------------------------------------|
| <code>-help</code>            | Prints out the command usage.                         |
| <code>-fall</code>            | Specifies the ideal latency for the falling edge.     |
| <code>value</code>            | Specifies the ideal latency value.                    |
| <code>-max</code>             | Specifies the ideal latency for the maximum corner.   |
| <code>-min</code>             | Specifies the ideal latency for the minimum corner.   |
| <code>pin_or_port_list</code> | Specifies a list of objects - instance pins or ports. |
| <code>-rise</code>            | Specifies the ideal latency for the rising edge.      |

## Examples

- The following command adds an ideal latency of 1.5ns to the input pin A of cell FE\_OFC413\_scan\_se:

```
tempus > set_ideal_latency 1.5 FE_OFC413_scan_se/A
```

Please note that the above command will only be valid if the pin is part of an ideal network.

Now, this ideal latency value can be observed in the output of the following `report_timing` command:

```
tempus > report_timing -through FE_OFC413_scan_se/A
```

```

- `report_timing`
- `set_ideal_network`

## set\_ideal\_network

```
set_ideal_network
[-help]
obj_list
[-no_propagate]
```

Identifies driver pins or ports as sources of an ideal network. By default, all pins and nets in the transitive fanout of the specified port or driver pin are marked as ideal. Ideal network marking normally propagates through combinational cells and stops at sequential cells.

This command is not view/mode-based - it applies to all the active views.

The `set_ideal_network` command sets 0 slew for bi-directional pins. This ensures that unnecessary DRV violations do not occur.

### Parameters

|                            |                                                              |
|----------------------------|--------------------------------------------------------------|
| <code>-help</code>         | Prints out the command usage.                                |
| <code>-no_propagate</code> | Prevents propagation through transitive fanout.              |
| <i>obj_list</i>            | Specifies a list of objects - instance pins, ports, or nets. |

## Examples

- The following command marks the fanout of the input port scan\_se as an ideal network:

```
tempus > set_ideal_network scan_se
```

This can be observed in the output of below mentioned report\_timing command where the whole fanout of 'scan\_se' is considered as ideal :

```
tempus > report_timing -from scan_se
```

```
Path 1: MET Setup Check with Pin RESULTS_CONV_INST/r697_reg[12]/CK

## set\_ideal\_transition

```
set_ideal_transition
[-help]
[-min]
[-max]
[-rise]
[-fall]
value
pin_or_port_list
```

Specifies the ideal transition to use for input or output leaf-cell pins and top-level ports that are part of an ideal network. These set a point delay on the specified object.

**Note:** You should specify `set_ideal_transition` with `set_ideal_network` to view ideal transition result.

### Parameters

|                               |                                                        |
|-------------------------------|--------------------------------------------------------|
| <code>-help</code>            | Prints out the command usage.                          |
| <code>-fall</code>            | Specifies the ideal transition for the falling edge.   |
| <code>-max</code>             | Specifies the ideal transition for the maximum corner. |
| <code>-min</code>             | Specifies the ideal transition for the minimum corner. |
| <code>pin_or_port_list</code> | Specifies a list of objects - instance pins or ports.  |
| <code>-rise</code>            | Specifies the ideal transition for the rising edge.    |
| <code>value</code>            | Specifies the ideal transition time.                   |

### Examples

Here are some examples.

- The following command specifies the ideal transition of 0.5ns on pin `scan_se`:

```
tempus > set_ideal_transition 0.5 scan_se
```

Please note that this ideal transition would only be applicable if the pin is part of an ideal network, otherwise this value would be ignored.

This transition will be propagated through the ideal network as shown in the output of the

following `report_timing` command:

```
tempus > report_timing -from scan_se
```

```
Path 1: MET Setup Check with Pin RESULTS_CONV_INST/r697_reg[14]/CK

## Related Commands

- `reset_ideal_transition`

## set\_input\_delay

```
set_input_delay
[-help]
[-clock clock_name]
[-clock_fall]
[-rise] [-fall]
[-max] [-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-reference_pin pin_name]
[-level_sensitive]
value
pin_or_port_list
```

Defines the arrival time relative to a clock edge on input ports or internal input pins. This input path delay models the delay from an external register to an input port of the module.

If the input delay is not specified on an input port, it is assumed to be zero.

**Note:** If the `set_input_delay` constraint is added incrementally in SI mode, an explicit `update_timing -full` command is required (before `report_timing` or `report_constraint`) for SI full accuracy.

### Parameters

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                    | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-add_delay</code>               | Adds delay information to the existing input delay. The additional delay information can be for multiple paths relative to different clocks or clock edges leading to an input port or internal input pins. If you do not use the <code>-add_delay</code> option, the software uses the last <code>set_input_delay</code> related to a pin when there are multiple <code>set_input_delay</code> statements for the same pin. |
| <code>-clock <i>clock_name</i></code> | Specifies that the delay is relative to the rising edge of the given clock. If you do not specify the <code>-clock</code> parameter, the delay is relative to time zero. To specify a delay relative to the falling edge of the clock, use the <code>-clock_fall</code> option with the <code>-clock</code> option.<br><br>When you specify multiple clocks, an error occurs and the constraint is ignored.                  |

|                                        |                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-clock_fall</code>               | <p>Specifies that the delay is relative to the falling edge of the clock. You must specify the <code>-clock</code> parameter with this parameter.</p> <p><i>Default:</i> Delay is relative to the rising edge.</p> <p>You cannot specify the <code>-clock_fall</code> parameter without the <code>-clock</code> parameter.</p>                                         |
| <code>value</code>                     | <p>Specifies the value for the path delay.</p>                                                                                                                                                                                                                                                                                                                         |
| <code>-fall</code>                     | <p>Specifies that the input delay refers to the falling edge of the signal at specified ports or pins. If you do not specify the <code>-fall</code> option, the input delay applies to both the edges.</p>                                                                                                                                                             |
| <code>-level_sensitive</code>          | <p>Models input delay that is launched by a positive level sensitive latch. Use the <code>-clock</code> parameter to model a positive level sensitive latch, or the <code>-clock_fall</code> parameter to model a negative level sensitive latch.</p> <p>You cannot specify the <code>-level_sensitive</code> parameter without the <code>-clock</code> parameter.</p> |
| <code>-max</code>                      | <p>Specifies that the delay refers to the setup analysis. If you do not specify the <code>-max</code> parameter, the input delay applies to both setup and hold analysis.</p> <p><b>Note:</b> If for a specific clock the maximum delay is less than the minimum delay, then during analysis the software makes the maximum delay equal to the minimum delay.</p>      |
| <code>-min</code>                      | <p>Specifies that the delay refers to the hold analysis. If you do not specify the <code>-min</code> parameter, the input delay applies to both setup and hold analysis.</p>                                                                                                                                                                                           |
| <code>-network_latency_included</code> | <p>Specifies that the clock network latency should not be added to the input delay value. If you do not specify this option, the clock network latency of the related clock is added to the input delay value. This parameter has no effect if the specified clock is in propagated mode.</p>                                                                          |
| <code>pin_or_port_list</code>          | <p>Specifies a list of input port or pin names. The <code>pin_or_port_list</code> argument can be a collection.</p>                                                                                                                                                                                                                                                    |

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-reference_pin <i>pin_name</i></code> | <p>Adds source and network latency of the specified reference pin to the input delay value in propagated mode. A reference pin is a leaf pin in the fanout cone of the clock source of the clock that you specify using the <code>-clock</code> parameter.</p> <p>You cannot use the <code>-reference_pin</code> parameter to specify multiple pins. If specified, the command issues a warning and accepts the first pin.</p> <p>You cannot use the <code>-reference_pin</code> parameter with the <code>-network_latency_included</code> or <code>-source_latency_included</code> parameters.</p> <p>You cannot use the <code>-reference_pin</code> parameter to specify hierarchical pins.</p> |
| <code>-rise</code>                          | <p>Specifies that input delay refers to the rising edge of the signal at the specified ports or pins. If you do not specify the <code>-rise</code> option, the input delay applies to the both edges.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-source_latency_included</code>       | <p>Specifies that the clock source latency should not be added to the input delay value.</p> <p>With different delay values for <code>-rise/-fall</code> and <code>-min/-max</code>, only the last specified combination of <code>-network_latency_included</code> and <code>-source_latency_included</code> parameters is honored. The specified combination can be one of the following:</p> <ol style="list-style-type: none"> <li>Either <code>-network_latency_included</code> or <code>-source_latency_included</code></li> <li>Both of these</li> <li>None of these</li> </ol>                                                                                                             |

## Examples

- The following command sets an input delay of 1.0 for all inputs in the current design relative to the rising edge of the `CLK1` clock:

```
tempus > set_input_delay -clock CLK1 1.0 [all_inputs]
```

- The following command sets an input delay of 2.0 for the input `IN1` port relative to the falling edge of the `CLK1` clock:

```
tempus > set_input_delay -clock CLK1 2.0 -clock_fall { IN1 }
```

- The following example shows an input `IN1` port that is constrained by both the rising edge and the falling edge of the same `CLK1` clock. The `-add_delay` option prevents the second `set_input_delay` statement from overwriting the first `set_input_delay`:

```
tempus > set_input_delay -clock CLK1 1.0 { IN1 }
```

```
tempus > set_input_delay -clock CLK1 -clock_fall -add_delay 2.0 { IN1 }
```

- When multiple `-min` and `-max` values are specified relative to the same clock using the `-add_delay` option at the same port or pin, the worst case value for each case is used. For the `-min` case the smallest value is retained, and for the `-max` case the largest value is retained. For example, the input delay value of 1.0 is stored for the shortest path and the value of 4.0 is stored for the longest path in the following example:

```
tempus > set_input_delay -min -clock CLK1 1.0 { IN1 }
tempus > set_input_delay -min -clock CLK1 2.0 -add_delay { IN1 }
tempus > set_input_delay -max -clock CLK1 3.0 -add_delay { IN1 }
tempus > set_input_delay -max -clock CLK1 4.0 -add_delay { IN1 }
```

## set\_input\_transition

```
set_input_transition
[-help]
[-min]
[-max]
[-rise]
[-fall]
value
port_list
```

Specifies the slew time for a port on the top level module. This command is useful only in specifying a hard ramp signal as if the port were driven by a very powerful driver. The command does not change the arrival time of an input, but changes the slew time used to compute the delay of the cell on the sink of a net. If you do not define transition using the `set_input_transition` command, the software uses the default input port transition defined in the configuration file. The default value is 0.1ps. You can also set the `delaycal_input_transition_delay` attribute to override the default value.

The `set_input_transition` command specification for clock signals does not impact setup/hold timing calculations.

**Note:** The `set_input_transition` command does not support internal pins. For specifying transition on internal pins use the `set_annotated_transition` command.

**Note:** The most recent command settings (of `set_driving_cell`, `set_input_transition`, or `set_drive`) that are applied to a port will be considered - the software will override the previous commands.

The `set_input_threshold` command should be issued after the `set_lib_binding_by_voltage` command.

### Parameters

|               |                                                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help         | Prints out the command usage.                                                                                                                                                         |
| -fall   -rise | Specifies that the slew time should be applied to the rising edge or the falling edge of the signal (data or clock). If neither time is specified, the default is to use both.        |
| -min   -max   | Indicates whether the slew times are with respect to the early (hold) or the late (setup) time checks of the data signal. If neither option is specified, the default is to use both. |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>port_list</code> | <p>Specifies the list of ports for which the slew time is specified.</p> <p><b>Note:</b> You cannot use the <code>set_input_transition</code> command to specify transition on output ports.</p> <p><b>Note:</b> When you use both <code>set_input_transition</code> and <code>set_annotated_transition</code> commands for specifying transition on input ports, the worst value is used as the transition value.</p> |
| <code>value</code>     | <p>Specifies the transition time.</p>                                                                                                                                                                                                                                                                                                                                                                                  |

## Examples

- The following command specifies the slew time of 0.5 on port `input3`.

```
set_input_transition 0.5 input3
```

## Related Commands

- `report_ports`
- `set_driving_cell`
- `set_drive`
- `set_clock_transition`

## set\_load

```
set_load
[-help]
[-max] [-min]
[-pin_load]
[-wire_load]
[-subtract_pin_load]
capacitance_value
port_or_net_list
```

Sets the specified capacitance on the defined ports (or nets) of the top cell.

The specified capacitance overrides the capacitance from the wire load models and SPEF.

You can use the [report\\_ports](#) command to view capacitance of asserted ports. The pin load appears in the report as `port_cap` in the assertion column and the wire load appears as `port_wire_cap` in the assertion column.

In the timing report (generated using the [report\\_timing](#) command), the load value for ports is displayed as a sum of the `set_load` value on a port and the existing wire capacitance obtained from the SPEF file, and pin capacitance obtained from the library files.

### Parameters

|                                |                                                                                                                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>             | Prints out the command usage.                                                                                                                                                                                         |
| <code>capacitance_value</code> | Specifies the value for the capacitance. The capacitance is in units from the target technology library.                                                                                                              |
| <code>-min</code>              | Specifies the minimum capacitance. The minimum capacitance is used to compute best-case delays in BcWc analysis mode and early path delays in OCV analysis mode.                                                      |
| <code>-max</code>              | Specifies the maximum capacitance. The maximum capacitance is used to compute worst-case delays in BcWc analysis mode and late path delays in OCV mode. It is also used to check the maximum capacitance design rule. |
| <code>port_or_net_list</code>  | Specifies a list of ports or nets in the top cell.                                                                                                                                                                    |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-pin_load</code>          | <p>Specifies the external pin capacitance for a port. You can use this parameter for ports only.</p> <p>For ports, the asserted capacitance is either the external pin capacitance when the <code>-pin_load</code> parameter is specified, or the external wire capacitance when the <code>-wire_load</code> parameter is specified, or the total external capacitance when neither option is specified.</p>                                                                                                              |
| <code>-subtract_pin_load</code> | <p>This parameter can be used only if nets are specified in the object list.</p> <p>When this parameter is specified, the total net capacitance value will be the same as set by the <code>set_load capacitance_value object_list</code> command.</p> <p>When this parameter is not specified, the asserted load value will only change the wire capacitance value from the SPEF. The total net capacitance value will be the <code>set_load</code> capacitance value plus the pin capacitance from the library file.</p> |
| <code>-wire_load</code>         | <p>Interprets the specified capacitance as the external wire capacitance of the port. Use this option only for ports. Use this option with the <code>port_net_list</code> argument if the list contains only ports.</p>                                                                                                                                                                                                                                                                                                   |

## Examples

Here are some examples.

- The following command sets an external minimum pin capacitance of 1.5 units on the `in1 in2` ports:  

```
tempus > set_load 1.5 -min -pin_load [get_ports {in1 in2}]
```
- The following command sets an external minimum wire capacitance of 1.2 units on the `in1 in2` ports:  

```
tempus > set_load 1.2 -min -wire_load [get_ports {in1 in2}]
```
- The following command sets an external maximum pin capacitance of 2.6 units on the `in1 in2` ports:  

```
tempus > set_load 2.6 -max -pin_load [get_ports {in1 in2}]
```
- The following command sets an external maximum wire capacitance of 3.0 units on the `in1 in2` ports:  

```
tempus > set_load 3.0 -max -wire_load [get_ports {in1 in2}]
```
- The following command reports the capacitances set on the ports, as shown in the example below:  

```
tempus > report_ports -pin [get_ports {in1}]
```

# set\_max\_capacitance

```
set_max_capacitance
[-help]
limit
obj_list
[-clock_path]
[-data_path]
[-fall]
[-override]
[-rise]
```

Sets the maximum capacitance limit on the specified ports of the top cell, the specified designs, or clock waveforms.

When set on a port, the total capacitance of the net connected to that port must be less than or equal to the specified limit. Maximum capacitance limits also come from library objects, which is the default maximum capacitance limit of libraries and the maximum capacitance limit on library cell pins. Pins in the design inherit the limits from libraries.

**Note:** The limit set on the top cell applies to its ports. Thus, if maximum capacitance limits are set on the top cell and its ports, the most constraining limit will apply to the ports.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_max_capacitance` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

## Parameters

|                          |                                                                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>       | Prints out the command usage.                                                                                                                                                 |
| <code>-clock_path</code> | Applies the max capacitance constraint only to pins in the clock network of the clocks defined in the object list.                                                            |
| <code>-data_path</code>  | Applies the max capacitance constraint only to data path pins, where the path is launched by the clocks defined in the object list.                                           |
| <code>-fall</code>       | Applies the max capacitance constraint only to falling capacitance.                                                                                                           |
| <code>-rise</code>       | Applies the max capacitance constraint only to rising capacitance.                                                                                                            |
| <i>limit</i>             | Specifies the value for the minimum capacitance limit. The limit must be greater than or equal to zero. The limit is in capacitance units from the target technology library. |

|                  |                                                                                                                                                                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>obj_list</i>  | Specifies a list of objects - ports, instance pins, library cell pins, designs, and/or clock waveform.                                                                                                                                                                                          |
| <i>-override</i> | Overrides the capacitance limit from other sources, such as, library or constraints.<br><br>This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. |

## Examples

Here are some examples.

- The following example sets a maximum capacitance limit of 1.2 units on all the ports of the top cell and a maximum capacitance limit of 0.5 units on the port named `d_out`:

```
tempus > set_max_capacitance 1.2 [get_ports *]
tempus > set_max_capacitance 0.5 d_out
```

- The following example uses the `report_ports` command to show the maximum capacitance limit set on ports:

```
tempus > set_max_capacitance 0.9 [get_ports *]
tempus > report_ports -type port_cap_limit -pin [get_ports *]
```

The following report is displayed:

```

Pin Dir Assertion Value
Name

CLK2 IN port_cap_limit (: 0.900)
CLK1 IN port_cap_limit (: 0.900)
in2 IN port_cap_limit (: 0.900)
in1 IN port_cap_limit (: 0.900)
out2 OUT port_cap_limit (: 0.900)
out1 OUT port_cap_limit (: 0.900)

```

# set\_max\_delay

```
set_max_delay
[-help]
[-combinational_from_to | -ignore_clock_latency]
[{-from | -rise_from | -fall_from} from_list]
[-no_segment]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]
[-comment string]
[-rise]
[-fall]
value
```

Specifies a maximum delay for a timing path. The `set_max_delay` command takes precedence over other path exceptions specified for the same path, except for the `set_false_path` command.

Use either the `-from`, `-to`, or `-through` option with the `set_max_delay` command to identify the paths. Specifying both the `-from` and `-to` options identifies a path with specific starting and ending points.

When you specify a sequential cell name for starting point of the timing path, the valid path starts from the `clk` pin. This means the latency and delay from `clk` to output `Q` is also included in the delay. For path segmentation, you can specify the path to start from `Q` output of the register by adding `/Q` after the cell name. In this case, path from `clk` to `Q` is not considered in the calculation.

Use only one `-from`, `-rise_from`, or `-fall_from`, `-to`, `-rise_to`, or `-fall_to` parameter per command. You can use multiple `-through` parameters in the same command.

**Note:** If the `set_max_delay` constraint is added incrementally in SI mode, an explicit `update_timing -full` command is required (before `report_timing` or `report_constraint`) for SI full accuracy.

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-<br/>combinational_from_to</code> | <p>Defines a path defined by <code>-from/to</code> pins as combinational.</p> <p>When this parameter is used, the path between the <code>-from/to</code> pins is treated as combinational, that is, both the source/capture clock latencies are excluded from slack computation. The presence of <code>-from/to</code> pins is required for this option to take effect; the <code>-from/to</code> pins can be sequential or combinational start/end pins.</p> <p>The <code>-combinational_from_to</code> parameter will be deprecated in a future release. The <code>-combinational_from_to</code> parameter will continue to work in the current release, but for compatibility with future releases you should migrate your scripts to use the <code>-ignore_clock_latency</code> parameter.</p> <p>You can use the following attributes to match the semantics between the <code>-ignore_clock_latency</code> and <code>-combinational_from_to</code> parameters:</p> <ul style="list-style-type: none"><li>• <code>timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency</code></li><li>• <code>timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency</code></li></ul> |
| <code>-comment <i>string</i></code>      | <p>Allows you to insert comments. The comments are read but are ignored with a warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-fall</code>                       | <p>Apply the assertion at the falling edge of the signal on the path endpoints.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

A pin is an inferred data pin if it is associated with one of the following:</li> <li>• Signal end of setup check</li> <li>• Signal end of hold check</li> <li>• Signal end of non-sequential setup check</li> <li>• Signal end of non-sequential hold check</li> <li>• Signal end of removal check</li> <li>• Signal end of recovery check</li> <li>• Pin associated with <i>set_external_delay</i></li> <li>• Data pin of clock gating cell</li> </ul> <p>Select from one of the following:</p> |
|                                              | <p><b>-to:</b> Applies the maximum delay constraint to all paths ending in the <i>-to</i> pin. If the clock is specified as the <i>-to</i> object, all primary outputs and registers clocked by the clock are used as endpoint.</p> <p>By default, the <i>-to</i> option applies the constraint to both the rising and the falling edges of the signal.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                              | <p><b>-rise_to:</b> Applies the maximum delay constraint at the rising edge of the signal to pins.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                              | <p><b>-fall_to:</b> Applies the maximum delay constraint at the falling edge of the signal to pins.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <pre>value</pre>                             | <p>Specifies the maximum delay value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Examples

- The following command specifies that all paths from `in1` to `out1` must have delays less than 10 units:

```
tempus > set_max_delay 10 -from in1 -to out1
```

## set\_max\_fanout

```
set_max_fanout
[-help]
limit
obj_list
[-override]
```

Sets the maximum fanout load limit constraint on the specified instance pins, library cell pins, ports of the top cell, clock waveforms, and/or specified modules. When pins of cell instances have their own maximum constraint defined in the library, the software will pick the more aggressive value of the two.

When set on a port, the fanout load of the net connected to the port must be less than or equal to the specified limit value to meet the constraint. The fanout load of a net is the sum of the fanout loads of the pins driven by the net. When set on a module, the limit applies to all the nets of that module. Libraries and library cell pins may also have the maximum fanout load limit. In this case the most constraining limit is applied to the nets.

Use the `report_ports -type fanout_load_limit` command to view the maximum fanout load limits set on ports of the top cell.

Fanout load limit can be asserted on input ports, output pins, bidirectional pins, or ports and library pins. You cannot apply the constraint on input pins and output ports.

### Parameters

|                        |                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>     | Prints out the command usage.                                                                                                                                                                                                                                                               |
| <i>limit</i>           | Specifies the value of the maximum fanout load limit constraint. This is a float number and it must be greater than or equal to zero.                                                                                                                                                       |
| <i>obj_list</i>        | Specifies a list of objects - input ports, instance output pins, designs, or library cell output pins.                                                                                                                                                                                      |
| <code>-override</code> | Overrides the maximum fanout limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. |

### Examples

- The following example sets a maximum fanout load limit of 5.0 units on all the ports of the top cell:

```
tempus > set_max_fanout 5.0 [get_ports *]
```

- The following example shows a report of the maximum fanout load limit set on ports using the `report_ports` command:

```
tempus > set_max_fanout 5.0 [get_ports *]
tempus > report_ports -type fanout_load_limit -pin [get_ports *]
```

The following report is displayed:

```

Pin Dir Assertion Value
Name

CLK2 IN fanout_load_limit 5.000
CLK1 IN fanout_load_limit 5.000
in2 IN fanout_load_limit 5.000
in1 IN fanout_load_limit 5.000

```

- The following example sets a maximum fanout load limit of 5.0 units on all the ports of the top cell:

```
tempus > set_max_fanout 5.0 [get_ports *]
```

- The following example shows a report of the maximum fanout load limit set on ports using the `report_ports` command, as shown in the example below:

```
tempus > set_max_fanout 5.0 [get_ports *] report_ports -type fanout_load_limit -pin
[get_ports *]
```

## set\_max\_time\_borrow

```
set_max_time_borrow
[-help]
value
obj_list
[-interface]
```

Specifies the maximum time that can be borrowed by one stage from the next logic stage following a latch to meet timing constraints. Time borrowing is sometimes called cycle stealing. Time borrowing is performed automatically when performing timing analysis.

Use the `set_max_time_borrow` assertion on pins or waveforms. If the assertion is placed on a clock waveform, all latches triggered by this clock signal get the specified maximum time borrow limit. If both the clock waveform arriving at the clock pin of a latch and the clock pin itself have time borrow limit constraints, the maximum borrow limit on the latch is decided by the assertion on the latch clock pin.

### Parameters

|                         |                                                                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>      | Prints out the command usage.                                                                                                                                                                                                                    |
| <code>-interface</code> | Specifies the IO paths for which maximum time will be borrowed.                                                                                                                                                                                  |
| <code>value</code>      | Specifies the maximum amount of time that can be borrowed. The minimum value allowed is 0, which disables time borrowing. The maximum allowed is equal to the pulse width minus the setup time: $\text{Max} = \text{pulse width} - \text{setup}$ |
| <code>obj_list</code>   | Specifies the list of instance pins, instances, or clocks on which the borrow value is applied. The <i>object_list</i> argument can be a collection.                                                                                             |

### Examples

Here are some examples.

- tempus > set\_max\_time\_borrow 2 [get\_cells {ff1 ff2 ff3}]
- tempus > set\_max\_time\_borrow 1.7 I4/g
- tempus > set\_max\_time\_borrow 2.5 [get\_clocks CLK1]

## Related Commands

- `get_clocks`
- `get_cells`

- `reset_max_time_borrow`

# set\_max\_transition

```
set_max_transition
[-help]
[-clock_path]
[-data_path]
[-rise]
[-fall]
[-override]
transition_limit
object_list
```

Sets the maximum slew time limit (transition) on the specified ports of the top cell, and/or clock waveforms.

When set on a port, the slew time at the port must be less than or equal to the specified limit. Maximum transition limits on pins can come from library objects, which are the default maximum transition of the libraries or maximum transition on library cell pins. In this case, the most constraining limit, which is the smallest, will apply on pins and ports.

Use the `report_ports -type slew_limit` command to view the maximum transition limits set on ports of the top cell.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

## Parameters

|                          |                                                                                                                                                                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>       | Outputs a brief description that includes type and default information for each <code>set_max_transition</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man set_max_transition</code> . |
| <code>-clock_path</code> | Applies the max transition constraint only to pins in the clock network of the clocks defined in the object list.                                                                                                                                          |
| <code>-data_path</code>  | Applies the max transition constraint only to data path pins, where the path is launched by the clocks defined in the object list.                                                                                                                         |
| <code>-fall</code>       | Applies the max transition constraint only to falling transitions.                                                                                                                                                                                         |
| <code>object_list</code> | Specifies the list of objects - ports, instance pins, library cell pins, clock waveforms, or current design.                                                                                                                                               |
| <code>-rise</code>       | Applies the max transition constraint only to rising transitions.                                                                                                                                                                                          |

|                               |                                                                                                                                                                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>transition_limit</code> | Specifies the value of the maximum slew time limit (maximum transition), which must be greater than or equal to zero. The maximum slew time limit is in time units in the current session.                                                                                                     |
| <code>-override</code>        | Overrides the transition limit from other sources, such as, library or constraints.<br><br>This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. |

## Examples

Here are some examples.

- The following command sets a maximum transition limit of 0.9 units on all the ports of the top cell:

```
tempus > set_max_transition 0.9 [get_ports *]
```

- The following example shows a report of the maximum transition limit set on ports using the `report_ports` command, as shown in the example below:

```
tempus > set_max_transition 0.9 [get_ports *]
```

```
tempus > report_ports -type slew_limit -pin [get_ports *]
```

The following report is displayed:

| Pin Name | Dir | Assertion  | Value        |
|----------|-----|------------|--------------|
| in1      | IN  | slew_limit | ( : 0.9000 ) |
| in2      | IN  | slew_limit | ( : 0.9000 ) |
| out1     | OUT | slew_limit | ( : 0.9000 ) |
| out2     | OUT | slew_limit | ( : 0.9000 ) |
| out3     | OUT | slew_limit | ( : 0.9000 ) |
| out4     | OUT | slew_limit | ( : 0.9000 ) |

- The following command sets the maximum transition limit of 0.001 units on pins in the `all_clocks` collection:

```
tempus > set_max_transition 0.001 -clock_path [all_clocks]
```

- The following command sets the transitions to the specified value for your entire design:

```
tempus > set_max_transition value [current_design]
```

- The following command impacts `report_constraint` output as shown below:

```
set_max_transition 0.01 TDP_COE_INST/TDP_COE_GL_INST/p82
```

The following command shows output as shown below:

```
report_constraint -all_violators -drv_violation_type max_transition
```

```
#####
```

```
format : frame 0 : split 0
```

```
Check type : max_transition
```

## set\_min\_capacitance

```
set_min_capacitance
[-help]
[-clock_path]
[-data_path]
[-rise]
[-fall]
[-override]
capacitance_limit
obj_list
```

Sets the minimum capacitance limit on the specified ports of the top timing module and/or clock waveforms.

When set on a port, the total capacitance of the net connected to that port must be greater than or equal to the specified limit. When set on a module, the limit applies to all the nets of that module. The total capacitance of each net of the module must be greater than or equal the specified limit. The minimum capacitance limit also comes from library objects, which is the default minimum capacitance limit of libraries and minimum capacitance limit on library cell pins. Pins in the design inherit the limits from libraries. When limits are set on a module and the limit is inherited from libraries, the most constraining limit, which is the largest limit, is used.

**Note:** The limit set on the top timing module applies to its ports. Thus, if minimum capacitance limits are set on the top timing module and its ports, the most constraining limit will apply to the ports.

Use the `report_ports -type port_cap_limit` command to view the minimum capacitance limits set on ports.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_min_capacitance` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

**Note:** This command syntax is applicable only when the flow-compatible mode is on.

## Parameters

|                                |                                                                                                                                                                                                                                                                                                                |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>             | Prints out the command usage.                                                                                                                                                                                                                                                                                  |
| <code>-clock_path</code>       | Specifies all pins that are in the network of the specific clocks in the object list.                                                                                                                                                                                                                          |
| <code>-data_path</code>        | Specifies all pins that are in the data paths launched by the specific clocks in the object list.                                                                                                                                                                                                              |
| <code>-fall</code>             | Specifies falling capacitance.                                                                                                                                                                                                                                                                                 |
| <code>-rise</code>             | Specifies rising capacitance for all selected pins.                                                                                                                                                                                                                                                            |
| <code>capacitance_limit</code> | Specifies the value for the minimum capacitance limit. The limit must be greater than or equal to zero. The limit is in capacitance units from the target technology library.                                                                                                                                  |
| <code>obj_list</code>          | Specifies the list of objects - ports, instance pins, library cell pins, modules, and/or clock wave forms.                                                                                                                                                                                                     |
| <code>-override</code>         | <p>Overrides the minimum capacitance limit from other sources, such as, library or constraints.</p> <p>This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting.</p> |

## Examples

- The following example sets a minimum capacitance limit of 0.02 units on all the ports of the top timing module and a minimum capacitance limit of 0.05 units on the top timing module:

```
tempus > set_min_capacitance 0.02 [get_ports *]
tempus > set_min_capacitance 0.05 [current_design]
```

The limit used for ports is 0.05, which is the most restrictive limit set on the top timing module (0.05) and the limit set on ports (0.02).

- The following example uses the `report_port` command to show the minimum capacitance limit set on ports:

```
tempus > set_min_capacitance 0.02 [get_ports *]
tempus > report_ports -type port_cap_limit -pin [get_ports *]
```

- The following command sets the minimum capacitance limit of 0.001 units on pins in the `all_clocks` collection (see example below):

```
tempus > set_min_capacitance 0.001 -data_path [all_clocks]
```

```
tempus > report_ports -type port_cap_limit -pin [get_ports *]
```

The following report is displayed:

| Pin<br>Name | Dir | Assertion      | Value             |
|-------------|-----|----------------|-------------------|
| CLK2        | IN  | port_cap_limit | ( 0.020 : 0.900 ) |
| CLK1        | IN  | port_cap_limit | ( 0.020 : 0.900 ) |
| in2         | IN  | port_cap_limit | ( 0.020 : 0.900 ) |
| in1         | IN  | port_cap_limit | ( 0.020 : 0.900 ) |
| out2        | OUT | port_cap_limit | ( 0.020 : 0.900 ) |
| out1        | OUT | port_cap_limit | ( 0.020 : 0.900 ) |

## set\_min\_delay

```
set_min_delay
[-help]
[-combinational_from_to | -ignore_clock_latency]
[{-from | -rise_from | -fall_from} from_list]
[-no_segment]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]
[-rise]
[-fall]
[-comment string]
value
```

Specifies a minimum delay for a timing path. The `set_min_delay` command takes precedence over other path exceptions specified for the same path, except for `set_false_path` command specifications.

Use either the `-from`, `-to`, or `-through` option with the `set_min_delay` command to identify the paths. Specifying both the `-from` and `-to` options identifies a path with specific starting and ending points. If a clock is specified as the `-to` object, all primary outputs and registers clocked by that clock are used as an endpoint.

When you specify a sequential cell name for starting point of the timing path, the valid path starts from the clk pin. This means the latency and delay from clk to output Q is also included in the delay. For path segmentation, you can specify the path to start from Q output of the register by adding `/Q` after the cell name. In this case, path from clk to Q is not considered in the calculation. For example, in the following set of commands, the valid path starts from different points:

```
set_min_delay 0.66 -from TR1/BR1 -to BLK/BR1/D
set_min_delay 0.66 -from TR1/BR1/Q -to BLK/BR1/D
```

For the first command, the valid path starts from clk, and for the second command the valid path starts from the Q output. In the second case, the path from clk to Q is not considered. For an example of the results generated for paths with and without path segmentation, see [Examples](#).

Use only one `-from`, `-rise_from`, or `-fall_from`, `-to`, `-rise_to`, or `-fall_to` parameter per command. You can use multiple `-through` parameters in the same command.

### Parameters

| <p><i>value</i></p>                                   | <p>Specifies the minimum delay value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Examples

- The following command specifies a minimum delay of 2.5 for paths from in1 to out1:

```
tempus > set_min_delay 2.5 -from in1 -to out1
```

- The following commands show the timing report output without path segmentation:

```
tempus > set_min_delay 3 -from f0 -to f1/D
```

```
tempus > report_timing -early -from f0 -to f1/D
```

# set\_min\_fanout

```
set_min_fanout
[-help]
limit
obj_list
[-override]
```

Sets the minimum fanout load limit constraint on the specified input ports of the top cell.

When set on a port, the fanout load of the net connected to the port must be greater than or equal to the specified limit value to meet the constraint. The fanout load of a net is the sum of the fanout loads of the pins driven by the net. When set on a module, the limit applies to all the nets of that module. The libraries and library cell pins may also have the minimum fanout load limit. In this case the most constraining limit is applied to the nets.

The constraint will not be used in optimizations.

Fanout load limit can be asserted on input ports, output pins, bidirectional pins, or ports and library pins. The constraint cannot be applied on input pins and output ports.

## Parameters

|               |                                                                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help         | Prints out the command usage.                                                                                                                                                                                                                                                                      |
| limit         | Specifies the value of the minimum fanout load limit constraint. The specified value must be greater than or equal to zero.                                                                                                                                                                        |
| obj_list      | Specifies a list of objects - ports, instance pins, modules, or library cell pins.                                                                                                                                                                                                                 |
| -<br>override | Overrides the minimum fanout limit from other sources, such as, library or constraints.<br><br>This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. |

## Examples

- The following example sets a minimum fanout load limit of 0.001 units on all the ports of the top cell:  

```
tempus > set_min_fanout 0.001 [get_ports *]
```
- The following example shows a report of the minimum fanout load limit set on ports using the report\_ports command, as shown in the following example:

```
tempus > set_min_fanout 5.0 [get_ports *]
tempus > report_ports -type fanout_load_limit -pin [get_ports *]
```

The following report is displayed:

| ----- |     |                   |       |
|-------|-----|-------------------|-------|
| Pin   | Dir | Assertion         | Value |
| Name  |     |                   |       |
| ----- |     |                   |       |
| CLK2  | IN  | fanout_load_limit | 5.000 |
| CLK1  | IN  | fanout_load_limit | 5.000 |
| in2   | IN  | fanout_load_limit | 5.000 |
| in1   | IN  | fanout_load_limit | 5.000 |
| ----- |     |                   |       |

# set\_min\_pulse\_width

```
set_min_pulse_width
[-help]
[-low]
[-high]
[-waveform_aware_type {absolute | source_width_ratio}]
value
object_list
```

Selects the most restrictive value when multiple minimum pulse width checks are set.

**Note:** The `timing_disable_lib_pulse_width_checks` attribute has no effect on pulse width checks created by the `set_min_pulse_width` command.

## Parameters

|                                                                                |                                                                                                                                                                                                                                                                                                                    |

| <code>-help</code>                                                             | Prints out the command usage.                                                                                                                                                                                                                                                                                      |
| <code>-high</code>                                                             | Applies the minimum pulse width check to high signal levels only. If neither the <code>-low</code> or <code>-high</code> option is specified, the value is applied to both low and high signal levels.                                                                                                             |
| <code>list</code>                                                              | Specifies a list of pins or clock waveforms to which the minimum pulse width check is to be applied. If the list is not specified, the minimum pulse width check applies to all the pins in the clock tree of the current design. If a clock waveform is specified, all the pins driven by the clock are affected. |
| <code>-low</code>                                                              | Applies the minimum pulse width check to low signal levels only. If neither the <code>-low</code> or <code>-high</code> option is specified, the value is applied to both low and high signal levels.                                                                                                              |
| <code>object_list</code>                                                       | Specifies list of objects: pins, ports, or clocks.                                                                                                                                                                                                                                                                 |
| <code>value</code>                                                             | Specifies a non-negative floating minimum pulse width check value. No default value is assumed for minimum pulse width checks.                                                                                                                                                                                     |
| <code>-<br/>waveform_aware_type<br/>{absolute  <br/>source_width_ratio}</code> | Specifies the type of waveform-aware pulse width check to apply as <code>absolute</code> or <code>source_width_ratio</code> .                                                                                                                                                                                      |

## Examples

- The following command sets a minimum pulse width, both low and high, check of 1.0 to the clock network of the current design:

```
tempus > set_min_pulse_width 1.0
```

- The following command sets a minimum pulse width low check of 2.0 to all the pins clocked by the CLK1 clock:

```
tempus > set_min_pulse_width -low 2.0 [get_clocks CLK1]
```

- The following command sets a minimum pulse width -high check of 1.0 to the CP clock pin of register ff1, as shown in the following example:

```
tempus > set_min_pulse_width 0.5 u55/CK -low
tempus > set_min_pulse_width 1.0 u55/CK -high
tempus > report_min_pulse_width -pin u55/CK
```

```

## set\_min\_transition

```
set_min_transition
[-help]
[-clock_path]
[-data_path]
[-rise]
[-fall]
[-override]
limit
obj_list
```

Sets the minimum slew time limit (transition) on the specified ports of the top timing module and/or clock waveforms.

When set on a port, the slew time at the port must be greater than or equal to the specified limit. When set on a module, the limit applies to all the pins in the module and its ports if the module is the top timing module. The minimum transition limits on pins can come from library objects, which are the default minimum transition of the libraries or minimum transition on library cell pins. In this case, the most constraining limit, which is the largest, will apply on pins and ports.

Use the `report_ports -type slew_limit` command to view the minimum transition limits set on ports of the top timing module.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_min_transition` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

**Note:** This command syntax is applicable only when the flow-compatible mode is on.

## Parameters

|                          |                                                                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>       | Prints out the command usage.                                                                                                                                                                                                                                                                                 |
| <code>-clock_path</code> | Specifies all pins that are in the network of the specific clocks in the object list.                                                                                                                                                                                                                         |
| <code>-data_path</code>  | Specifies all pins that are in the data paths launched by the specific clocks in the object list.                                                                                                                                                                                                             |
| <code>-fall</code>       | Specifies falling capacitance.                                                                                                                                                                                                                                                                                |
| <code>obj_list</code>    | Specifies the list of objects - ports, instance pins, library cell pins, modules, and/or clock waveforms.                                                                                                                                                                                                     |
| <code>-override</code>   | <p>Overrides the minimum transition limit from other sources, such as, library or constraints.</p> <p>This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting.</p> |
| <code>-rise</code>       | Specifies rising capacitance for all selected pins.                                                                                                                                                                                                                                                           |
| <code>limit</code>       | <p>Specifies the value of the minimum slew time limit (minimum transition). The minimum slew time limit is in time units from the target technology library.</p> <p>Transition limit value (float, required)</p> <p>Min=-1000000</p> <p>Max=1000000</p>                                                       |

## Examples

- The following example sets a minimum transition limit of 0.9 units on all the ports of the top timing module, and a minimum transition limit of 0.7 units on the top timing module:

```
tempus > set_min_transition 0.9 [get_ports *]
tempus > set_min_transition 0.7 [current_design]
```

The minimum limit that applies to ports is 0.9, which is the largest constraints value.

- The following example shows a report of the minimum transition limit set on ports using the `report_ports` command, as shown in the example below:

```
tempus > set_min_transition 0.9 [get_ports *]
```

```
tempus > report_ports -type slew_limit -pin [get_ports *]
```

The following report is displayed:

```

Pin Dir Assertion Value
Name

CLK2 IN slew_limit (0.900 :)
CLK1 IN slew_limit (0.900 :)
in2 IN slew_limit (0.900 :)
in1 IN slew_limit (0.900 :)
out2 OUT slew_limit (0.900 :)
out1 OUT slew_limit (0.900 :)

tempus > report_constraint -drv_violation_type min_transition

Check type : min_transition

Pin : CLK4

Transition Time: 0.003
- min_transition: 0.900

slack : -0.897 (VIOLATED)
```

## set\_mode

```
set_mode
[-help]
[-type cell]
mode_list
inst_list
```

Specifies the Liberty timing library modes to be active for a specific instance.

A library mode is a subset of active timing arcs that is defined in the timing library. Library modes are similar to conditional timing arcs, but do not require the application of constants to set. Instead of changing a cell's mode by applying constants to its input pins, you can use the `set_mode` command to refer to sets of active arcs by name (such as `READ` or `WRITE`, for a memory cell).

By default, all library modes in the timing library are active. If you specify one or more library modes using the `set_mode` command, only the timing arcs consistent with the specified mode(s) are active for the instance. All other library modes become inactive.

To reset the library modes for an instance, use the `reset_mode` command.

### Parameters

|                         |                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>      | Prints out the command usage.                                                                                                                                                                                                                                            |
| <code>inst_list</code>  | Specifies the instances to which to apply the library mode.                                                                                                                                                                                                              |
| <code>mode_list</code>  | Specifies the name of the library mode value defined in the timing library. You can specify one or more mode values, but only one mode value per defined mode group in the Liberty library.                                                                              |
| <code>-type cell</code> | <p>Sets the library mode at the instance level.</p> <p><b>Note:</b> Setting the library mode at the instance level is the only form of <code>set_mode</code> that is currently supported. This parameter exists to support constraints coming from external sources.</p> |

## Examples

- The following command specifies that only the timing arcs consistent with the test\_A library mode are active for instances of b1 (The test\_A library mode is made inactive.):

```
tempus > set_mode test_mode [get_cells b1]
```

The following command reports the status of all library modes associated with b1 . It shows that test\_A is active and test\_B is inactive.

```
tempus > report_mode b1
```

```

Mode Group test_mode of b1

Mode Status Condition
Name

test_B Inactive !(Y)
test_A ACTIVE Y

```

If you specify the `report_inactive_arcs` command, the report shows the disabled arcs for the b1 instance are from the `test_mode` library mode:

```

Flags : const propagated constant
 snipped loop snipped arcs
 disable set_disable_timing
 disable_clock_gating set_disable_clock_gating
 library_disable set_disable_cell_timing
 Missing_Phase No Arc Phase Data
From To DisableType ArcType Reason

u8/CK ^ u8/D ^ const hold_rising_clk_rise u8/D = 1
u8/CK ^ u8/D v const hold_falling_clk_rise u8/D = 1
u8/CK ^ u8/D ^ const setup_rising_clk_rise u8/D = 1
u8/CK ^ u8/D v const setup_falling_clk_rise u8/D = 1

```

## Related Commands

# set\_multicycle\_path

```
set_multicycle_path
[-help]
<number_of_cycles>
[-comment <string>]
[-fall]
[-fall_through <through_list>]
[-hold]
[-rise]
[-rise_through <through_list>]
[-setup]
[-through <through_list>]
[-start | -end]
[-from <from_list> | -rise_from <from_list> | -fall_from <from_list>]
[-to <to_list>] > | -rise_to <to_list> | -fall_to <to_list>]>
```

Specifies multicycle paths between specific timing paths in a design or between clock domains. The multicycle paths are timing paths that require more than one clock period for execution. By default, all the paths are considered as one cycle paths for setup and hold check evaluation. The `set_multicycle_path` command allows you specify additional cycles for the paths.

## Parameters

|                                                   |                                                                                                                                                                                                                 |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                | Prints out the command usage.                                                                                                                                                                                   |
| <code>number_of_cycles</code>                     | Specifies the number of cycles allowed for the path.                                                                                                                                                            |
| <code>-comment string</code>                      | Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints. |
| <code>-fall</code>                                | Applies the assertion at the falling edge of the signal on the path endpoints.                                                                                                                                  |
| <code>[-fall_through &lt;through_list&gt;]</code> | Applies the assertion at the falling edge of the signal on the through pins                                                                                                                                     |

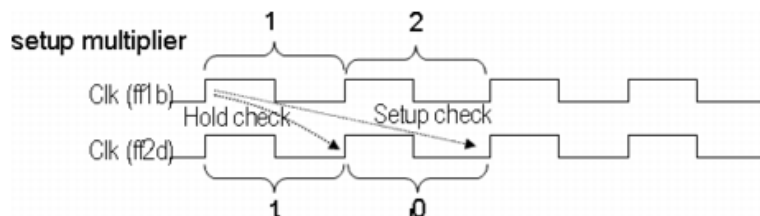

|                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <p>-from<br/>&lt;from_list&gt;   -<br/>rise_from<br/>&lt;from_list&gt;   -<br/>fall_from<br/>&lt;from_list&gt;</p> | <p>Specifies the clocks, ports, pins, or sequential instances that are at the start of the multicycle paths.</p> <p>The port direction can be either input or inout. Pins must be valid path startpoints such as sequential instance clock pins, latch data pins or pins on which input delays have been specified. Intermediate hierarchical pins should not be specified as -from in path exceptions unless those are valid begin points. Even if the specified constraint is accepted, timing analysis will ignore such (set_false_path/set_multicycle_path) constraints. The <i>from_list</i> variable can contain either collection IDs or object names.</p> <p>If the -from option is used without the -to option, all paths originating from the from_list are multicycle paths.</p> <p>Use either the -from, -to, or -through option with the set_multicycle_path command to identify the paths.</p> <p>Specifying both the -from and -to options identifies a path with specific starting and ending points.</p> <p>Use only one -from, -rise_from, or -fall_from option per command.</p> |
| <p>-hold   -setup</p>                                                                                              | <p>Specifies whether the multicycle adjustment applies to setup/hold check.</p> <p>The -setup parameter applies multicycles to setup check. The hold check is affected but the hold multiplier does not change.</p> <p>The -hold parameter applies multicycles to hold check only.</p> <p><i>Default:</i> If you do not specify -setup or -hold parameter, the software considers the specified multicycle value for setup check and uses 0 for the hold check.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <p>-rise</p>                                                                                                       | <p>Applies the assertion at the rising edge of the signal on the path endpoints.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <p>-rise_through<br/>&lt;through_list&gt;</p>                                                                      | <p>Applies the assertion at the rising edge of the signal on the through pins.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <p>-start   -end</p>                                                                                               | <p>Specifies whether the multicycle adjustment is to be applied relative to the starting clock edge for the path or relative to the ending clock edge for the path.</p> <p>Use these options for multiple clocks designs. By default, the setup check is relative to the end clock and the hold check is relative to the start clock.</p> <p><b>Note:</b> The -start and -end parameters are mutually exclusive; you cannot specify them together.</p> <p>You can set the timing_enable_sdc_compatible_data_check_mcp global variable to true to enable checking for SDC compatible data checks. When the -start parameter is specified, the parameter reverses the reference clock by one clock cycle.</p>                                                                                                                                                                                                                                                                                                                                                                                        |

|                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>-through &lt;through_list&gt;</pre>                                              | <p>Applies the assertion to both the rising and the falling edges. This parameter specifies the ports, pins, instances, or nets that the path goes through.</p> <p>The pins can be on intermediate hierarchical boundaries. The <i>through_list</i> variable can contain either collection IDs or object names.</p> <p>When used without the <i>-from</i> or <i>-to</i> option, all paths that go through the <i>-through</i> pins are multicycle paths. When used with both the <i>-from</i> and <i>-to</i> options, any path starting at any pin on the <i>-from</i> list and going through any point on the <i>-through</i> pin list and going to any point on the <i>-to</i> list is affected by the assertion.</p> <p>You can use only one <i>-from</i> and <i>-to</i> option, but you can specify several <i>-through</i> options in the same command.</p> <p>By default, the <i>-through</i> option applies the assertion to both the rising and the falling edges. Using the <i>-rise_through</i> option applies the assertion at the rising edge of the signal on the through pins. Using the <i>-fall_through</i> option applies the assertion at the falling edge of the signal on the through pins.</p> |
| <pre>-to &lt;to_list&gt;   -rise_to &lt;to_list&gt;   - fall_to &lt;to_list&gt;</pre> | <p>Specifies the clocks, ports, pins, or sequential instances that are at the end of the multicycle paths.</p> <p>The port direction can be either output or inout. Pins must be valid path endpoints such as sequential instance data pins or pins on which output delays have been specified. Pins can be on intermediate hierarchical boundaries. The <i>to_list</i> variable can contain either collection IDs or object names.</p> <p>If the <i>-to</i> option is used without the <i>-from</i> option, all paths ending in the <i>-to</i> pin list are multicycle paths. Use only one <i>-to</i> option per command.</p> <p>Use only one <i>-to</i>, <i>-rise_to</i>, or <i>-fall_to</i> option per command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Examples

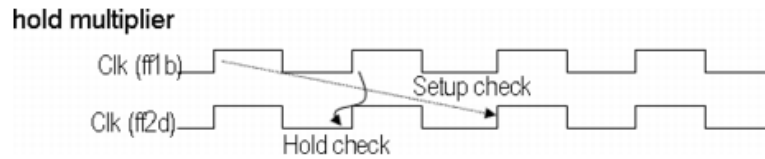

- The following command sets all paths between ff1b + ff2d to two cycles for setup:

```
set_multicycle_path -setup 2 -from {ff1b} -to {ff2d}
```

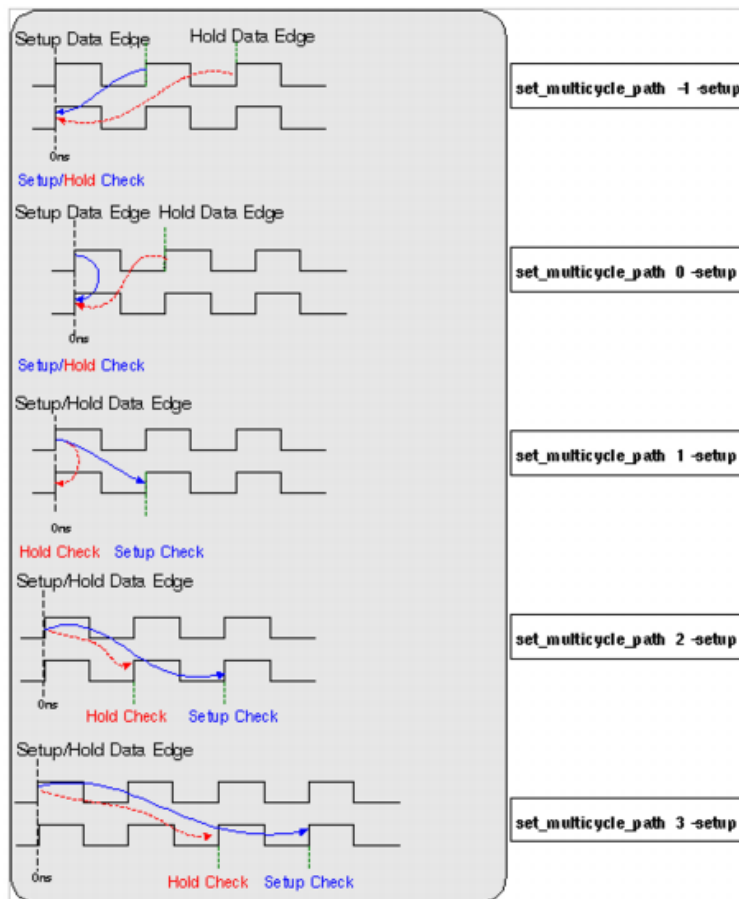

- The following command moves hold check to start clock preceding edge:

```
set_multicycle_path -hold 1 -from {ff1b} -to {ff2d}
```

- The following commands show setup multiplier values from -1 to 3:

```
set_multicycle_path -1 -setup
set_multicycle_path 0 -setup
set_multicycle_path 1 -setup
set_multicycle_path 2 -setup
set_multicycle_path 3 -setup
```

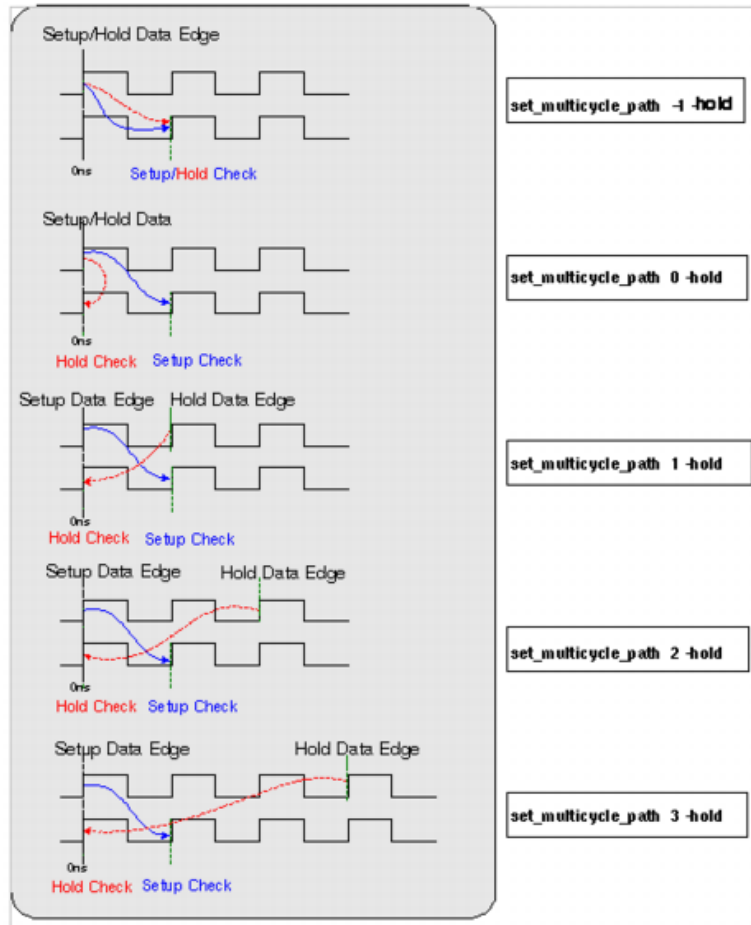

- The following commands show hold multiplier values from -1 to 3:

```
set_multicycle_path -1 -hold
```

```
set_multicycle_path 0 -hold
set_multicycle_path 1 -hold
set_multicycle_path 2 -hold
set_multicycle_path 3 -hold
```

## set\_normalized\_driver\_waveform\_lib

```
set_normalized_driver_waveform_lib
[-help]
[-fall_waveform string]
[-rise_waveform string]
-ref_lib string
-libs string
```

Specifies normalized driver waveform for a library. The normalized driver waveform given in the reference library is applied to all the specified libraries.

**Note:** This command must be specified after the design is loaded. For this command to take effect, you should set the `timing_generate_normalized_driver_waveform` attribute to `false` before loading libraries.

### Parameters

|                              |                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| -help                        | Prints out the command usage.                                                                       |
| -fall_waveform <i>string</i> | Specifies the name of the fall normalized driver waveform.                                          |
| -libs <i>string</i>          | Specifies a list of space separated libraries to which normalized driver waveform is to be applied. |
| -ref_lib <i>string</i>       | Specifies the reference library from which normalized driver waveform is to be selected.            |
| -rise_waveform <i>string</i> | Specifies the name of the rise normalized driver waveform.                                          |

### Examples

- The following example shows that normalized driver waveform given in \$libDir/libs/ref.lib will be applied to all the cells in \$libDir/1.lib \$testDir/2.lib \$libDir/libs/3.lib:

```
tempus > set_normalized_driver_waveform_lib -libs "$libDir/1.lib $testDir/2.lib
$libDir/libs/3.lib" -ref_lib $libDir/libs/ref.lib
```

## set\_output\_delay

```
set_output_delay
[-help]
-clock clock_name
[-clock_fall]
[-rise]
[-fall]
[-max]
[-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-reference_pin pin_name]
[-level_sensitive]
[-group_path group_name]
value
pin_or_port_list
```

Specifies the data required time on output ports, hierarchical ports, or internal output pins.

### Parameters

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                    | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                   |
| -add_delay               | Adds delay information to the existing output delay. The additional delay information can be for multiple paths relative to different clocks or clock edges leading to an input port or internal input pins. If you do not use the <code>-add_delay</code> option, the software uses the last <code>set_output_delay</code> related to a pin when there are multiple <code>set_output_delay</code> statements for the same pin. |
| -clock <i>clock_name</i> | <p>Specifies that the delay is relative to the specified clock.</p> <p>You cannot use the <code>set_output_delay</code> command without the <code>-clock</code> parameter. Such constraints are accepted but are ignored during timing analysis.</p> <p>When you specify multiple clocks, an error occurs and the constraint is ignored.</p>                                                                                    |

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-clock_fall</code>               | <p>Specifies that the delays are with respect to the falling edge of the clock waveform. If you do not specify the <code>-clock_fall</code> option, the delay is with respect to the rising edge of the clock waveform.</p> <p>You cannot specify the <code>-clock_fall</code> parameter without the <code>-clock</code> parameter.</p>                                                                                                                                                                                                                                                                                                                                                     |
| <code>value</code>                     | Specifies the value for the path delay.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-fall</code>                     | Specifies that the output delay refers to the falling edge of the signal at specified ports or pins. If you do not specify the <code>-fall</code> option, the output delay applies to both the edges.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>-group_path group_name</code>    | <p>Specifies the group name where paths ending at the specified ports or pins are to be added.</p> <p>The <code>-group_path</code> parameter is not honored in multi-mode multi-corner (MMMC) designs. If specified, a warning is issued and the constraints are applied as if the <code>-group_path</code> parameter is not specified.</p>                                                                                                                                                                                                                                                                                                                                                 |
| <code>-level_sensitive</code>          | <p>Models output delay that is captured by a positive level sensitive latch. For setup checks, the timing system checks the arrival time at the output port with the opening edge of the latch. The timing system treats any arrival time exceeding the opening edge as negative slack. For hold checks, the timing system performs the checks with respect to the closing edge of the latch.</p> <p>Use the <code>-clock</code> parameter to model a positive level sensitive latch, or the <code>-clock_fall</code> parameter to model a negative level sensitive latch.</p> <p>You cannot use the <code>-level_sensitive</code> parameter without the <code>-clock</code> parameter.</p> |
| <code>-max</code>                      | Specifies that the delay refers to the setup analysis. If you do not specify the <code>-max</code> parameter, the output delay applies to both setup and hold analysis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-min</code>                      | Specifies that the delay refers to the hold analysis. If you do not specify the <code>-min</code> parameter, the output delay applies to both setup and hold analysis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-network_latency_included</code> | Specifies that the clock network latency should not be added to the output delay value. If you do not specify this option, the clock network latency of the related clock is added to the output delay value. This parameter has no effect if the specified clock is in propagated mode.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>pin_or_port_list</code>          | Specifies a list of output port or pin names. The <code>pin_or_port_list</code> argument can be a collection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-reference_pin <i>pin_name</i></code> | <p>Adds source and network latency of the specified reference pin to the output delay value in propagated mode. A reference pin is a leaf pin in the fanout cone of the clock source of the clock that you specify using the <code>-clock</code> parameter.</p> <p>You cannot specify multiple pins for <code>-reference_pin</code> parameter. The command issues a warning and accepts the first pin.</p> <p>You cannot use the <code>-reference_pin</code> parameter with the <code>-network_latency_included</code> or <code>-source_latency_included</code> parameters.</p> <p>You cannot use the <code>-reference_pin</code> parameter to specify hierarchical pins.</p> |
| <code>-rise</code>                          | <p>Specifies that output delay refers to the rising edge of the signal at the specified ports or pins. If you do not specify the <code>-rise</code> option, the output delay applies to the both edges.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-source_latency_included</code>       | <p>Specifies that the clock source latency should not be added to the output delay value.</p> <p>With different delay values for <code>-rise/-fall</code> and <code>-min/-max</code>, only the last specified combination of <code>-network_latency_included</code> and <code>-source_latency_included</code> parameters is honored. The specified combination can be one of the following:</p> <ol style="list-style-type: none"> <li>Either <code>-network_latency_included</code> or <code>-source_latency_included</code></li> <li>Both the parameters</li> <li>None of these</li> </ol>                                                                                  |

## Examples

- The following example sets the input and output delays for the bidirectional INOUT2 port. The input signal arrives at INOUT2 at 4.5 units after the falling edge of CLKB. The output signal is required at INOUT2 at 2.5 units before the rising edge of CLKD:

```
tempus > set_input_delay 4.5 -clock CLKB -clock_fall { INOUT2 }
tempus > set_output_delay 2.5 -clock CLKD { INOUT2 }
```

- The following example shows how to use the `-group_path` option to add ports into a named group:

```
tempus > set_output_delay 2.5 -max -clock CLK -group_path busC {busC[*]}
```

## Related Commands

## set\_pll\_timing

```
set_pll_timing
[-help]
inst
-feedback_pin <feedback pin name>
-output_clock <clock name or ID>
-output_pin <output pin name>
[-reference_edge {rise | fall | both}]
-reference_pin <reference pin name>
```

This command identifies phase locked loop (PLL) insertion delays and the associated generated clock(s) that require adjustment. To remove the effect of clock tree latency, PLLs can be used to adjust the delay on the PLL output clock waveform so that the effective edges of the clock at the clock tree endpoints are aligned with the reference edges of the input clock to the PLL.

When you use the `set_pll_timing` command, the software uses the settings to automatically calculate and apply a delay offset to a PLL output clock to compensate for internal clock tree latency.

The `set_pll_timing` command works in conjunction with a generated clock definition to provide the correct clock timing at the output of the PLL. To use this command, you must first assert a generated clock on the `set_pll_timing -output_pin`. The `-source` option of the `create_generated_clock` command must also match the `-reference_pin` specified by the `set_pll_timing` command.

## Parameters

|                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                     | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>inst</code>                                      | Specifies the instance name or the object ID of a PLL cell, on the basis of which the reference pins, feedback pins, or the output pins will be searched.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-feedback_pin &lt;feedback pin name&gt;</code>   | Specifies the name of the PLL feedback pin.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-output_clock &lt;clock name or ID&gt;</code>    | Specifies the generated clock on the PLL output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-output_pin &lt;output pin name&gt;</code>       | Specifies the PLL clock output pin name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-reference_edge {rise   fall   both}</code>      | <p>Defines adjustment edge(s).</p> <p>When this parameter is specified, the software selects the edges of the clocks at the reference and feedback pins that need to be aligned. If the <code>rise</code> or <code>fall</code> option is specified, then the clock latency from that reference edge to the related edge at the feedback pin will be used. In this case, both the rise and fall edges will use the same latency adjustment.</p> <p>If both of these options are specified, then the software will measure separate latency adjustments for both the rise and fall edges.</p> <p><i>Default:</i> <code>rise</code></p> |
| <code>-reference_pin &lt;reference pin name&gt;</code> | Specifies the PLL reference pin name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Examples

Here are some examples.

- The following example shows the defined clocks in a sample design:

```
tempus > create_clock [get_ports {clk_in}] -name CLK -period 6 -waveform {0 3}
tempus > create_generated_clock -name GCLK1 -source [get_pins {mypll/CLK}] -multiply_by
1 -master_clock [get_clocks {CLK}] -add [get_pins {mypll/GCLK}]
```

The following `report_timing` command shows the insertion delay values at various points in the timing report:

```
tempus > report_timing -from_rise mypll/GCLK -to_rise mypll/CEN -point_to_point
```

```
Path 1:Endpoint: mypll/CEN (^) (unconstrained output)
Beginpoint: mypll/GCLK (^) triggered by leading edge of 'GCLK1'
Arrival Time 0.496
Analysis View: default_analysis_view_setup
```

| Pin           | Cell    | Delay  | Arrival Time | Generated Clock Adjustment |
|---------------|---------|--------|--------------|----------------------------|
| <hr/>         |         |        |              |                            |
| mypll/CLK     |         |        | 0.112        |                            |
| mypll/GCLK -> | PLL     | 0.133  | 0.246        | GCLK1 Adj. = 0.000         |
| clkTreeL0/Y   | CLKBUF1 | 0.139  | 0.385        |                            |
| clkTreeL1_1/Y | CLKBUF1 | 0.118  | 0.503        |                            |
| mypll/CEN ->  | PLL     | -0.007 | 0.496        |                            |

From the above table, it can be seen that the rise insertion delay of clock CLK at pin mypll/CLK is 0.112ns.

Now, the following command will adjust the source latency of clock GCLK1 such that the edges at mypll/CLK and mypll/CEN are aligned i.e. the clock's rising edge should reach mypll/CEN at 0.112ns only:

```
tempus > set_pll_timing [get_cells mypll] -reference_pin CLK -feedback_pin CEN -
output_pin GCLK -output_clock [get_clocks GCLK1]
```

- The following `report_timing` command shows the source latency of GCLK clock as -0.138ns, and the clock reaches mypll/CEN pin at 0.112ns (same as on mypll/CLK):

```
tempus > report_timing -from_rise mypll/GCLK -to_rise mypll/CEN -point_to_point
```

```
Path 1:Endpoint: mypll/CEN (^) (unconstrained output)
Beginpoint: mypll/GCLK (^) triggered by leading edge of 'GCLK1'
Arrival Time 0.112
Analysis View: default_analysis_view_setup
```

```
+ Source Insertion Delay 0.112
- PLL Feedback Delay 0.250
= Beginpoint Arrival Time -0.138
```

| Pin           | Cell    | Delay | Arrival Time | Generated Clock Adjustment |

- `create_generated_clock`
- `create_clock`
- `reset_pll_timing`

# set\_propagated\_clock

```
set_propagated_clock
[-help]
obj_list
```

Puts the `propagated_clock` assertion on the specified pin, port, or clock object. This will cause all clock endpoints in the fanout of the specified object to receive propagated clock timing unless there is a `set_clock_latency` with higher precedence. If there are multiple `set_clock_latency` and `set_propagated_clock` assertions between the clock waveform, clock root and clock endpoint, the closest assertion to the clock endpoint takes precedence.

There are two methods of clock propagation: depending on whether the clock is ideal or propagated.

- When a clock is ideal, the delay from a clock port to a register clock pin (network insertion delay) comes from design constraints using the `set_clock_latency` command.
- When a clock is propagated, the network insertion delay is computed from the actual gates and interconnects in the clock network.

To set the `propagated_clock` property on all clock waveform objects, use the following command:

```
set_propagated_clock [all_clocks]
```

When `set_propagated_clocks [all_clocks]` command is asserted, it will apply to all the currently defined clock waveform objects. This setting will not apply to clocks created later in the script. Whether all the clock endpoints receive propagated or ideal timing depends on the precedence of `set_clock_latency` in the fanout.

The `set_propagated_clock [all_clocks]` command puts the `propagated_clock` assertion on all clocks except virtual clocks. When you put the assertion on a real clock that is used to define I/O timing (with `set_input_delay -clock` or `set_output_delay -clock`), the software does not take the specified network latency into account. Instead, the software calculates the network latency, which changes the I/O timing. You can change this behavior by using the following attribute:

```
set_db timing_io_use_clock_network_latency always
```

You can use this command after creating the clock with the `create_clock` command.

## Parameters

|                       |                                                                                                                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>    | Prints out the command usage.                                                                                                                                                                                                                                                          |
| <code>obj_list</code> | Specifies the objects on which you want to put the <code>propagated_clock</code> assertion. The <code>pin_or_clock_list</code> argument can be a collection. When a pin is specified, it affects the propagation mode for all the registers in the transitive fanout (TFO) of the pin. |

## Examples

- The following command puts the propagated clock assertion on the clock waveform CLK1:

```
tempus > set_propagated_clock CLK1
```

- The following command puts the propagated clock assertion on all clock waveforms:

```
tempus > set_propagated_clock [all_clocks]
```

## Related Commands

# set\_property

```
set_property
[-help]
[-obj_type {object_type}]
{obj_list}
property_name
property_value
[-quiet]
```

Sets user-defined properties on objects.

The `set_property` command needs a property to be defined using the `define_property` command.

## Parameters

|                                      |                                                                      |
|--------------------------------------|----------------------------------------------------------------------|
| <code>-help</code>                   | Prints out the command usage.                                        |
| <code>obj_list</code>                | Specifies a list of objects on which the property is to be applied.  |
| <code>-obj_type {object_type}</code> | Specifies the type of object on which the property is to be defined. |
| <code>property_name</code>           | Specifies the name of the property.                                  |
| <code>property_value</code>          | Specifies the value of the property.                                 |
| <code>-quiet</code>                  | Specifies to exit quietly without issuing an error.                  |

## Examples

- The following command applies a user-defined property `slk` to pins `C1/A`:  
tempus > set\_property [get\_pins C1/A] slk 2
- The following command applies `aocv_weight` property to library arcs:  
tempus > set\_property [get\_lib\_arcs -of\_objects slow/INVX1] aocv\_weight 8

## Related Commands

# set\_pulse\_clock\_max\_transition

```
set_pulse_clock_max_transition
[-help]
limit
obj_list
[-transitive_fanout]
[-rise]
[-fall]
```

Sets the maximum pulse clock transition constraint on the specified pulse generator cells, pulse generator library cells, clocks, and/or current design.

## Parameters

|                        |                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------|
| -help                  | Prints out the command usage.                                                                                  |
| -fall                  | Sets transition limit value for falling transition.                                                            |
| <i>obj_list</i>        | Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design. |
| -rise                  | Sets transition limit value for rising transition.                                                             |
| <i>limit</i>           | Specifies the transition limit value.                                                                          |
| -<br>transitive_fanout | Specifies the transition limit value for transitive fanout.                                                    |

## Examples

- The following example sets the max pulse clock transition constraint of 0.1ns on the input pins of all the instances of the lib cell PULSE\_GEN\_00:

```
tempus > set_pulse_clock_max_transition 0.1 PULSE_GEN_00
```

- This constraint can be observed on the input pin 'A' of an instance 'pg\_inst' of this lib cell using the following command:

```
tempus > report_constraint pg_inst/A -drv_violation_type pulse_clock_max_transition
```

Fragmented output:

```
Check type : pulse_clock_max_transition_rise

```

```

Pin Name Required Actual Slack

pg_inst/A 0.100 0.030 0.070

Check type : pulse_clock_max_transition_fall

Pin Name Required Actual Slack

pg_inst/A 0.100 0.030 0.070
```

## Related Commands

- `get_clocks`
- `get_cells`
- `reset_pulse_clock_max_transition`

# set\_pulse\_clock\_max\_width

```
set_pulse_clock_max_width
[-help]
width
obj_list
[-transitive_fanout]
```

Sets the maximum pulse clock width constraint on the specified pulse generator cells, pulse generator library cells, clocks, and/or current design.

To report the maximum pulse clock width constraint, you can use the [report\\_constraint - check\\_type pulse\\_clock\\_max\\_width](#) command.

## Parameters

|                                      |                                                                                                                |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                   | Prints out the command usage.                                                                                  |
| <code>obj_list</code>                | Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design. |
| <code>width</code>                   | Specifies the pulse width value.                                                                               |
| <code>-<br/>transitive_fanout</code> | Specifies the pulse width value for transitive fanout.                                                         |

## Examples

- The following example sets the max pulse clock width constraint of 1 ns on the pulse generator instance 'pg\_inst':

```
tempus > set_pulse_clock_max_width 1 pg_inst
```

This constraint can be observed using the following command:

```
tempus > report_constraint pg_inst/Y -check_type pulse_clock_max_width
```

Fragmented output:

```

Pin Required Actual Pulse Slack Clock Type
Pulse Width Width

pg_inst/Y (high) 1.000 0.366 0.634 PG

```

## Related Commands

| <i>limit</i>           | Specifies the transition limit value.                                                                          |
| -<br>transitive_fanout | Specifies the transition limit value for transitive fanout.                                                    |

## Examples

- The following example sets the min pulse clock transition constraint of 0.05ns on the input pins of all the instances of the lib cell PULSE\_GEN\_00:

```
tempus > set_pulse_clock_min_transition 0.05 PULSE_GEN_00
```

This constraint can be observed on the input pin 'A' of an instance 'pg\_inst' of this lib cell using the following command:

```
tempus > report_constraint pg_inst/A -drv_violation_type pulse_clock_min_transition
```

Fragmented output:

```
Check type : pulse_clock_min_transition_rise

Pin Name Required Actual Slack

pg_inst/A 0.050 0.030 -0.020
Check type : pulse_clock_min_transition_fall

Pin Name Required Actual Slack

pg_inst/A 0.050 0.030 -0.020
```

## Related Commands

- `reset_pulse_clock_min_transition`
- `get_clocks`
- `get_cells`

# set\_pulse\_clock\_min\_width

```
set_pulse_clock_min_width
[-help]
pulse_width
object_list
[-transitive_fanout]
```

Sets the minimum pulse clock width constraint on the specified pulse generator cells, pulse generator library cells, clocks and/or current design.

When you set this constraint on a clock, the settings are applied to all the pulse generators that are driven by the clock. When this constraint is used for a design, the software applies the constraint to all the clock networks in the design.

The specified minimum pulse width is expected to be larger than the pulse width value. The width is defined when a clock object is created and its waveform is defined in the current design (using the `create_clock -waveform` parameter).

In case of conflicting minimum width constraints, the more restrictive constraint is used. When applied on a non-pulse generator object, or a non-clock target, this constraint has no effect.

**Note:** You must specify `set_interactive_constraint_modes` constraint prior to running the `set_pulse_clock_min_width` command.

## Parameters

|                                 |                                                                                                                |
|---------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>-help</code>              | Prints out the command usage.                                                                                  |
| <code>object_list</code>        | Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design. |
| <code>pulse_width</code>        | Specifies the minimum pulse width value.                                                                       |
| <code>-transitive_fanout</code> | Specifies the pulse width value for transitive fanout.                                                         |

## Examples

- The following example sets the min pulse clock width constraint of 0.3 ns on the pulse generator instance `pg_inst`:

```
tempus > set_pulse_clock_min_width 0.3 pg_inst
```

This constraint can be observed using the following command:

```
tempus > report_constraint pg_inst/Y -check_type pulse_clock_min_width
```

Fragmented output:

```

Pin Required Actual Pulse Slack Clock Type
Pulse Width Width

pg_inst/Y (high) 0.300 0.366 0.066 PG

```

## Related Commands

# set\_resistance

```
set_resistance
-help
[-max]
[-min]
value
net_list
```

Sets the wire resistance value on the specified nets of the top cell, which is used to compute the net delay of the specified nets. The resistance that you specify using this command overrides the resistance from wire load models and SPEF.

**Note:** In the best-case worst-case (BC-WC) analysis mode, the minimum resistance is used to compute the early path delay and the late path delay for the minimum corner. The maximum resistance is used to compute the early path delay and the late path delay for the maximum corner.

## Parameters

|                  |                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help            | Outputs a brief description that includes type and default information for each <code>set_resistance</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man set_resistance</code> . |
| -max             | Specifies that the asserted resistance is the maximum resistance.<br><i>Default:</i> If the <code>-max</code> (or <code>-min</code> ) parameter is not specified, the resistance value is used as both minimum and maximum resistance.             |
| -min             | Specifies that the asserted resistance is the minimum resistance.<br><i>Default:</i> If the <code>-min</code> (or <code>-max</code> ) parameter is not specified, the resistance value is used as both minimum and maximum resistance.             |
| net_list         | Specifies a list of nets on which the wire resistance is set.                                                                                                                                                                                      |
| resistance_value | Specifies the value for the wire resistance. This value (in units) is found in the target technology library.                                                                                                                                      |

## Examples

- The following example set the maximum wire resistance of 2.0 units on the net `n1`:  

```
tempus > set_resistance -max 2.0 [get_nets n1]
```
- The following example set the minimum wire resistance of 1.2 units and a maximum wire

resistance of 2.0 units on the net `n1`:

```
tempus > set_resistance 1.2 -min [get_nets n1]
```

```
tempus > set_resistance 2.0 -max [get_nets n1]
```

## Related Commands

- `reset_resistance`

## set\_sense

```
set_sense
[-help]
pin_or_port_list
[-clocks clock_list]
{[-positive | -negative | -stop_propagation | -clock_leaf]
[-type type_list]}
```

Selects which phase of the clock to filter at the specified point.

This command accepts timing arcs collection as a valid argument.

### Parameters

|                       |                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                 | Prints out the command usage.                                                                                                                                                                                                                                                                                                                                                                        |
| -clocks<br>clock_list | Specifies a list of clocks passing through a specified point to which the constraint applies.<br><br>When this parameter is not specified, the filtering of clock phase will be applicable to all the clocks passing through that specified point.<br><br>This parameter must be used with a specified pin name and one of the parameters : -positive, -negative, -stop_propagation, or -clock_leaf. |
| -clock_leaf           | When specified, the software propagates clock phases to the specified pin.                                                                                                                                                                                                                                                                                                                           |
| -negative             | Specifies that positive phase filtered clocks pass through pins in the pin_list.<br><b>Note:</b> The -positive, -negative and -stop_propagation parameters are mutually exclusive.                                                                                                                                                                                                                   |
| pin_or_port_list      | Specifies the list or collection of cell output pins. The unateness specified by the set_sense command is applied to clocks propagating through the specified point.                                                                                                                                                                                                                                 |
| -positive             | Specifies that negative phase filtered clocks pass through pins in the pin_list.<br><b>Note:</b> The -positive, -negative and -stop_propagation parameters are mutually exclusive.                                                                                                                                                                                                                   |
| -<br>stop_propagation | Stops the propagation of the specified clocks passing through the specified pins, or any phases that are specified by the -type parameter.<br><br><b>Note:</b> The -positive, -negative and -stop_propagation parameters are mutually exclusive.                                                                                                                                                     |

`-type type_list`

Applies clock sense to object types specified in the *type\_list*. The type list options are - all, clock, data, and clock\_source\_data.

These are explained below:

- **all:** Stops all phases from propagating. This is equivalent to specifying both the `clock` and `data` options.
- **clock:** Stops clock phases launched by clock(s) specified in the *clock\_list* from propagating.
- **data:** Stops all data phases launched by clock(s) specified in *clock\_list*, starting from the pins/ports specified in *pin\_or\_port\_list*. The objects in the *pin\_or\_port\_list* can be selected anywhere in the design - clock/data network.
- **clock\_source\_data:** Stops only clock source data phases from propagating.

**Notes:**

- The `-type clock` option should be used with the `-stop_propagation` parameter. When the `-type` parameter is not specified, then `set_sense -stop_propagation` will stop only the clock phases.
- The `-type data` option should be used with the `-stop_propagation` and `-clock` parameters.
- The `-type data` option is not supported with both `-positive` and `-negative` parameters.
- The `write_sdc` command will automatically add `-type clock` when `set_sense` is specified with the `-stop_propagation` parameter (without `-type`).

## Examples

- The following command allows the positive phase clock CLK1 to pass through CLKBUF1/Z and filters out the negative phase clock CLK1:

```
tempus > set_sense -positive -clocks CLK1 CLKBUF1/Z
```

- The following command stops clock phases starting from pin1:

```
tempus > set_sense pin1 -type {clock}
```

- The following command stops data phases based only on CK1 and CK2 starting from pin1:

```
tempus > set_sense pin1 -type {data} -clocks {CK1 CK2}
```

- The following command stops only the clock source data phases starting from pin1:

```
tempus > set_sense pin1 -type {clock_source_data}
```

- The following command stops the clock and clock source data phases:

```
tempus > set_sense pin1 -type {clock clock_source_data}
```

or

```
tempus > set_sense pin1 -stop_propagation
```

## Related Commands

# write\_annotated\_transition

```
write_annotated_transition
[-help]
out_file
[-direct]
[-exclude_ports]
[-include_output_pins]
[-max]
[-min]
[-view string]
```

Writes the value of transitions on each pin to an output file. You can either set the transitions using the `set_annotated_transition` command or the software computes them internally.

## Parameters

|                      |                                                                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                | Outputs a brief description that includes type and default information for each <code>write_annotated_transition</code> parameter.                                                                                      |
| -direct              | Refers the ports directly for which the annotated transition will be applied in the output SDC. This option removes the dependency of using the <code>get_ports</code> and <code>get_pins</code> commands.              |
| -include_output_pins | Writes the slews for input and output pins, and the output slew for bi-directional pins.<br><br>If this option is not specified, the software writes the slew for input pins and the input slew of bi-directional pins. |
| -min/-max            | Specifies whether to write out minimum or maximum transition.<br><i>Default:</i> Both minimum and maximum transitions are written out.                                                                                  |
| -exclude_ports       | Skips writing the transition values for the primary ports (input and output).                                                                                                                                           |
| out_file             | Specifies the name of the output file.                                                                                                                                                                                  |
| -view string         | Writes the transitions for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.                                                  |

## Examples

Here are some examples.

- The following command generates the output file `tran.rpt`:

```
tempus > write_annotated_transition -file tran.rpt
```

The following file is generated:

```
set_annotated_transition -rise -min 0.0278 [get_ports {sig_out4000}]
set_annotated_transition -fall -min 0.0275 [get_ports {sig_out4000}]
set_annotated_transition -rise -max 0.0278 [get_ports {sig_out4000}]
set_annotated_transition -fall -max 0.0275 [get_ports {sig_out4000}]
set_annotated_transition -rise -min 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -fall -min 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -rise -max 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -fall -max 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -rise -min 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -fall -min 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -rise -max 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -fall -max 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -rise -min 0.0453 [get_pins {buf_out5000/A}]
set_annotated_transition -fall -min 0.0418 [get_pins {buf_out5000/A}]
set_annotated_transition -rise -max 0.0453 [get_pins {buf_out5000/A}]
set_annotated_transition -fall -max 0.0418 [get_pins {buf_out5000/A}]
```

- The following command generates the minimum transitions in the output file, `min_tran.rpt`:

```
tempus > write_annotated_transition -min -file min_tran.rpt
```

The following file is generated:

```
set_annotated_transition -rise -min 0.0278 [get_ports {sig_out4000}]
set_annotated_transition -fall -min 0.0275 [get_ports {sig_out4000}]
set_annotated_transition -rise -min 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -fall -min 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -rise -min 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -fall -min 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -rise -min 0.0453 [get_pins {buf_out5000/A}]
set_annotated_transition -fall -min 0.0418 [get_pins {buf_out5000/A}]
```

- The following command generates the maximum transitions in the output file, `max_tran.rpt`:

```
tempus > write_annotated_transition -max -file max_tran.rpt
```

The following file is generated:

```
set_annotated_transition -rise -max 0.0278 [get_ports {sig_out4000}]
set_annotated_transition -fall -max 0.0275 [get_ports {sig_out4000}]
set_annotated_transition -rise -max 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -fall -max 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -rise -max 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -fall -max 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -rise -max 0.0453 [get_pins {buf_out5000/A}]
set_annotated_transition -fall -max 0.0418 [get_pins {buf_out5000/A}]
```

# write\_load

```
write_load
[-help]
load_file
[-direct]
[-exclude_zero_cap]
[-include_pin_cap]
[-wire_load]
```

Writes the capacitive loading on each net to an output file. By default, the capacitance value does not include the pin capacitance. You can either set the load using the `set_load` command or the software uses the load defined in the SPEF file.

**Note:** The command is currently not supported in multi-mode multi-corner mode.

## Parameters

|                   |                                                                                                                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help             | Prints out the command usage.                                                                                                                                                                                                              |
| -direct           | Refers the ports directly for which the capacitive loading will be written. This option removes the dependency of using the <code>get_nets</code> command.                                                                                 |
| -exclude_zero_cap | Excludes the nets not annotated in the design while writing out the capacitive loading on each net to the output file.                                                                                                                     |
| load_file         | Specifies the name of the output file.                                                                                                                                                                                                     |
| -help             | Outputs a brief description that includes type and default information for each <code>write_load</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man write_load</code> . |
| -include_pin_cap  | Includes the pin capacitance while writing out the capacitive loading on each net to the output file.                                                                                                                                      |
| -wire_load        | Adds option '-wire_load' to "set_load" (that is, <code>set_load -wire_load</code> ) only on the output (out) and bi-directional (inout) ports in the output file.                                                                          |

## Examples

- The following command writes the capacitive load in the report file `load.rpt`:

```
tempus > write_load -file load.rpt
```

The following report is generated:

```
set_load 1e-05 [get_nets {sig_out4000}]
set_load 0.00011 [get_nets {sig_in1000}]
set_load 0.00011 [get_nets {sig_in1001}]
set_load 0.00015 [get_nets {node_out6000}]
```

## analyze\_paths\_by\_bottleneck

```
analyze_paths_by_bottleneck
[-help]
{-category n | -delta_delay {worst|total}}
[-path_num m]
[-max_slack float]
[-min_slack float]
[-master master_category_name]
```

Creates categories according to the bottleneck analysis of the critical paths and fixes the violation according to the bottleneck information. Bottleneck Analysis detects the instances that are often involved in the critical paths in the design. Any change in timing for these instances impacts multiple critical paths in the design. Therefore you can use this information to change your design (floorplan, placement, constraints etc.) around these instances. The bottleneck analysis computes the number of occurrences that an instance appears in the paths that you display in the Timing Debug window, and provides the following output:

- Colors most used instance based on number of occurrences.
- Creates *n* number of path categories for the instances with the highest number of occurrences. *n* is the number you specify using the `-category` parameter.

Users can also perform bottleneck analysis of the critical paths based on incremental delay. Categories will be created based on the worst *m* paths with:

- The biggest worst `incr_delay` contribution
- The biggest total `incr_delay` contribution

The command can be applied wherever the user loads the machine readable timing report.

## Parameters

|                                           |                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                        | Outputs a brief description that includes type and default information for each <code>analyze_paths_by_bottleneck</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br><code>man analyze_paths_by_bottleneck</code> |
| <code>-category n</code>                  | Specifies the number of categories to be created for most occurring instances.                                                                                                                                                                                                                    |
| <code>-delta_delay {worst total}</code>   | Specifies that the categories are created based on worst <code>incr_delay</code> contribution or total <code>incr_delay</code> contribution.                                                                                                                                                      |
| <code>-master master_category_name</code> | Specifies that the analysis should be performed only for the specified <code>master</code> category.                                                                                                                                                                                              |
| <code>-max_slack float</code>             | Specifies the max slack value of the critical paths for bottleneck analysis based on <code>incr_delay</code> .                                                                                                                                                                                    |
| <code>-min_slack float</code>             | Specifies the min slack value of the critical paths for bottleneck analysis based on <code>incr_delay</code> .                                                                                                                                                                                    |
| <code>-path_num m</code>                  | Specifies the number of critical paths to be analyzed when performing bottleneck analysis based on <code>incr_delay</code> .                                                                                                                                                                      |

## Examples

- The following command creates path categories based on bottleneck analysis of the critical paths on the instances:

```
analyze_paths_by_bottleneck -category 2
```

The following categories are created: `BOT_instance1` and `BOT_instance2`. You can change the number of categories.

- The following command creates path categories based on bottleneck analysis of the critical 20 paths on the worst `incr_delay`:

```
analyze_paths_by_bottleneck -path_num 20 -delta_delay worst
```

The following category is created: `BOT_SI_WORST`.

## Related Commands

- [create\\_path\\_category](#)
- [delete\\_path\\_category](#)

# analyze\_paths\_by\_clock\_domain

```
analyze_paths_by_clock_domain
[-help]
[-include_edges]
[-include_views]
[include_mode]
[-master master_category_name]
```

To find the possible timing issues in clock combinations, the command creates categories according to launch clocks - capture clock combinations.

Following categories are created:

- Paths with clock fully contained in a single domain, clk1.
- Paths with clocks starting one clock domain and ending at another, clk1-> clk2.

The command can be applied wherever the user loads the machine readable timing report.

## Parameters

|                                     |                                                                                                                                                                                                                                                                                                       |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                               | Outputs a brief description that includes type and default information for each <code>analyze_paths_by_clock_domain</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br><code>man analyze_paths_by_clock_domain</code> |
| -include_edges                      | Considers leading or trailing edge of the clock while defining categories.                                                                                                                                                                                                                            |
| -include_mode                       | Considers constraint mode while defining categories.                                                                                                                                                                                                                                                  |
| -include_views                      | Considers analysis views while defining categories.                                                                                                                                                                                                                                                   |
| -master <i>master_category_name</i> |                                                                                                                                                                                                                                                                                                       |
|                                     | Specifies that the analysis should be performed only for the specified master category.                                                                                                                                                                                                               |

## Examples:

- The following command creates path categories based on clock domain analysis of the critical paths, and considers the edges of the clock:

```
analyze_paths_by_clock_domain -include_edges
```

- The following command creates path categories based on clock domain analysis of the critical paths, and considers the analysis views:

```
analyze_paths_by_clock_domain -include_views
```

## Related Commands

- [create\\_path\\_category](#)
- [delete\\_path\\_category](#)

# analyze\_paths\_by\_critical\_false\_path

```
analyze_paths_by_critical_false_path
[-help]
-critical_false_paths
{false_path_only | exclude_false_path}
[-master master_category_name]
```

Identifies violating false paths, which are paths that appear as violations but cannot be exercised due to the structure of the netlist, and creates a category that contains them. With this command the user can, in advance, categorize the critical false paths together to analyze them.

The command can be applied wherever the user loads the machine readable timing report.

## Parameters

|                                                           |                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                        | <p>Outputs a brief description that includes type and default information for each <code>analyze_paths_by_critical_false_path</code> parameter.</p> <p>For a detailed description of the command and all of its parameters, use the <code>man</code> command:</p> <pre>man analyze_paths_by_critical_false_path</pre>             |
| <code>-critical_false_paths</code>                        | <p>Specifies which paths to analyze.</p> <ul style="list-style-type: none"><li><code>false_path_only</code><br/>Includes only false paths when creating the category.</li><li><code>exclude_false_paths</code><br/>Excludes false paths when creating the category.</li></ul> <p><i>Default:</i> <code>false_path_only</code></p> |
| <code>-master</code><br><code>master_category_name</code> | <p>Specifies that the analysis should be performed only for the specified master category.</p>                                                                                                                                                                                                                                    |

## Examples:

- The following command creates path categories based on the critical false paths:  

```
analyze_paths_by_critical_false_path -critical_false_path\ false_path_only
```
- The following category is created: `default_report_false_path_only`

## Related Commands

- [create\\_path\\_category](#)
- [delete\\_path\\_category](#)

# analyze\_paths\_by\_default\_path\_group

```
analyze_paths_by_default_path_group
[-help]
[-master master_category_name]
[-predefined]
```

Categorizes the timing paths based on basic path groups. The basic path groups are fundamental to timing analysis and help the user easily observe the timing information of different basic path groups. For instance, if user is only concerned about the paths from registers to registers, the user can analyze the paths in the category REG -> REG. The basic path groups categories are:

- Register to register
- Input to register
- Register to output
- Input to output

The following categories are created:

- REG->REG
- IN->REG
- REG->OUT
- IN->OUT

Timing debug can also convert user defined path groups into path categories. The command can be applied wherever the user loads the machine readable timing report.

**Note:** If your design does not have paths belonging to a type of path group, the software will not create that category.

## Parameters

|                                        |                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                                  | Outputs a brief description that includes type and default information for each <code>analyze_paths_by_default_path_group</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br><code>man analyze_paths_by_default_path_group</code> |
| -master<br><i>master_category_name</i> | Specifies that the analysis should be performed only for the specified master category.                                                                                                                                                                                                                           |
| -predefined                            | Creates path categories for user defined path groups.                                                                                                                                                                                                                                                             |

## Examples

- The following command create path categories based on basic path groups:

```
analyze_paths_by_default_path_group
```

The following categories are created: REG->REG, IN->REG, REG->OUT, IN->OUT.

- The following command create path categories based on predefined path group "critical" :

```
group_path -name critical -from {ff*/CLK } -to {ff*/D} #create predefined path group
```

```
analyze_paths_by_default_path_group -predefined
```

The category "critical" will be created based on the predefined path group name.

## Related Commands

- [create\\_path\\_category](#)
- [delete\\_path\\_category](#)

## analyze\_paths\_by\_drv

```
analyze_paths_by_drv
[-help]
[[-load_cap_file capacitance_file] | [-generate_cap_file fileName]]
[[-load_transition_file transition_file] | [-generate_transition_file fileName]]
[[-load_fanout_file fanout_file] | [-generate_fanout_file fileName]]
[-master master_category_name]
```

Reads or generates a report containing max transition, max capacitance, and max fanout violations. Paths that are affected by the selected DRV type are grouped into a category. This command can be used if the user wants to debug the timing issues caused by DRV.

The command can be applied wherever the user loads the machine readable timing report.

## Parameters

|                                                    |                                                                                                                                                                                                                                                                                     |

|                                                    | Specifies that the analysis should be performed only for the specified master category.                                                                                                                                                                                             |

## Examples:

The following command generates DRV report files, then creates path categories based on the critical paths which are affected by DRV:

```
analyze_paths_by_drv -generate_cap_file capViolation.rpt
-generate_transition_file tranViolation.rpt
-generate_fanout_file fanoutViolation.rpt
```

## Related Commands

- [create\\_path\\_category](#)
- [delete\\_path\\_category](#)

# analyze\_paths\_by\_hier\_port

```
analyze_paths_by_hier_port
[-help]
[-generate_hier_file InstanceName_list]
[-load_hier_file file_name]
[-master master_category_name]
[-out_file]
```

Helps you to automatically group paths based on each hierarchical port of a given instance. You can use this command to perform the timing results analysis of a hierarchical design. For example, while looking at the setup/hold time at the same time of each port.

The command can be applied wherever the user loads the machine readable timing report.

## Parameters

```

Creates categories according to the hierarchical characteristics of the paths. User can use either a user specified floorplan file or current floorplan file of the design in memory and can create categories according to the hierarchy of the design. This way, the paths can be narrowed down to small group.

### Use Floorplan Plan:

The software automatically extracts partition-boundary information from guides, regions, and fences in the floorplan file. Optionally you can specify option to sort paths based on the macros in the floorplan file.

- All paths fully contained in a single partition, Ptn1.
- Paths starting in one partition and ending in another partition, Ptn1→Ptn2.
- Paths spanning several partitions, Ptn1→ Ptn2→Ptn3.
- Top-level inputs to partitions, INPUT→Ptn1.
- Paths from partitions to top-level outputs, Ptn1→OUTPUT.

### Use Current Floorplan:

This method categorizes paths based on the current floor plan of the design in memory. It will rely on the grouped/ungrouped as a basis for what level to view the hierarchy as well as what levels to create timing categories.

Grouped/ungrouped status of an Hinst means whether or not its children are shown on the floor plan view.

It categorizes paths starting and ending on/within these hierarchical entities:

- Port
- Hard Macro (ungrouped)
- Black Box (ungrouped)
- Hinst (regular, partition, Black Blob, or Flex Model) (highest grouped)
- Stdcell (ungrouped)

| -all                              | <p>Creates categories of paths within all types</p> <p><i>Default:</i> All types are categorized.</p>                                                                                                                                                                                             |
| -bbox_to_hinst                    | Creates categories of paths from black box to hierarchical instance.                                                                                                                                                                                                                              |
| -bbox_to_inst_group               | Creates categories of paths from black box to instance group.                                                                                                                                                                                                                                     |
| -bbox_to_port                     | Creates categories of paths from black box to port.                                                                                                                                                                                                                                               |
| -bbox_to_macro                    | Creates categories of paths from black box to macro.                                                                                                                                                                                                                                              |
| -blackbox_to_blackbox             | Creates categories of paths from black box to black box.                                                                                                                                                                                                                                          |
| -bbox_to_stdcell                  | Creates categories of paths from black box to standard cell.                                                                                                                                                                                                                                      |
| -floorplan_file<br>floorplan_file | <p>Specifies the name of the floorplan file.</p> <p><i>Default:</i> Uses the current floorplan file.</p>                                                                                                                                                                                          |
| -hinst_to_bbox                    | Creates categories of paths from hierarchical instance to black box.                                                                                                                                                                                                                              |
| -hinst_to_port                    | Creates categories of paths from hierarchical instance to port.                                                                                                                                                                                                                                   |
| -hinst_to_macro                   | Creates categories of paths from hierarchical instance to macro.                                                                                                                                                                                                                                  |
| -hinst_to_hinst                   | Creates categories of paths from hierarchical instance to hierarchical.                                                                                                                                                                                                                           |
| -hinst_to_inst_group              | Creates categories of paths from hierarchical instance to instance group.                                                                                                                                                                                                                         |

|                                                  |                                                                                                                             |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>-hinst_to_stdcell</code>                   | Creates categories of paths from hierarchical instance to standard cell.                                                    |
| <code>-include_macros</code>                     | Includes macros in addition to guides and fences for creating categories.<br><br><i>Default:</i> Macros are not considered. |
| <code>-inst_group_to_bbox</code>                 | Creates categories of paths from instance group to black box.                                                               |
| <code>-inst_group_to_hinst</code>                | Creates categories of paths from instance group to hierarchical instance.                                                   |
| <code>-inst_group_to_inst_group</code>           | Creates categories of paths from instance group to instance group.                                                          |
| <code>-inst_group_to_macro</code>                | Creates categories of paths from instance group to macro.                                                                   |
| <code>-inst_group_to_port</code>                 | Creates categories of paths from instance group to port.                                                                    |
| <code>-inst_group_to_stdcell</code>              | Creates categories of paths from instance group to standard cell.                                                           |
| <code>-macro_to_bbox</code>                      | Creates categories of paths from macro to black box.                                                                        |
| <code>-macro_to_port</code>                      | Creates categories of paths from macro to port.                                                                             |
| <code>-macro_to_macro</code>                     | Creates categories of paths from macro to macro.                                                                            |
| <code>-macro_to_hinst</code>                     | Creates categories of paths from macro to hierarchical instance.                                                            |
| <code>-macro_to_inst_group</code>                | Creates categories of paths from macro to instance group.                                                                   |
| <code>-macro_to_stdcell</code>                   | Creates categories of paths from macro to standard cell.                                                                    |
| <code>-macros <i>macro_list</i></code>           | Specifies the names of the macros to be used. Use this parameter with the <code>-partitions</code> parameter.               |
| <code>-master <i>master_category_name</i></code> | Specifies that the timing paths should be categorized only for the specified master category.                               |
| <code>-partitions <i>partition_list</i></code>   | Specifies the names of the partitions to consider for extracting hierarchical information.                                  |
| <code>-port_to_bbox</code>                       | Creates categories of paths from port to black box.                                                                         |
| <code>-port_to_port</code>                       | Creates categories of paths from port to port.                                                                              |
| <code>-port_to_macro</code>                      | Creates categories of paths from port to macro.                                                                             |
| <code>-port_to_hinst</code>                      | Creates categories of paths from port to hierarchical instance.                                                             |

|                                     |                                                                                                                                    |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>-port_to_inst_group</code>    | Creates categories of paths from port to instance group.                                                                           |
| <code>-port_to_stdcell</code>       | Creates categories of paths from port to std cell.                                                                                 |
| <code>-stdcell_to_bbox</code>       | Creates categories of paths from standard cell to black box.                                                                       |
| <code>-stdcell_to_port</code>       | Creates categories of paths from standard cell to port.                                                                            |
| <code>-stdcell_to_macro</code>      | Creates categories of paths from standard cell to macro.                                                                           |
| <code>-stdcell_to_hinst</code>      | Creates categories of paths from standard cell to hierarchical instance.                                                           |
| <code>-stdcell_to_inst_group</code> | Creates categories of paths from standard cell to instance group.                                                                  |
| <code>-stdcell_to_stdcell</code>    | Creates categories of paths from standard cell to standard cell.                                                                   |
| <code>-types type_list</code>       | Creates categories of paths within the <code>type_list</code> .<br>Valid types are: <code>port, macro, bbox, hinst, stdcell</code> |
| <code>-use_current_floorplan</code> | Uses the current floorplan.                                                                                                        |

## Examples:

- By default, it categorizes all paths inter/intra the 5 hierarchical entities by following command:  
`analyze_paths_by_hierarchy -use_current_floorplan -all`
- The following command categorizes all paths from "port" or to "port":  
`analyze_paths_by_hierarchy -use_current_floorplan -type port`

## Related Commands

- [`create\_path\_category`](#)
- [`delete\_path\_category`](#)

# analyze\_paths\_by\_view

```
analyze_paths_by_view
[-help]
[-prefix string]
[-master master_category_name]
```

Categorizes the timing paths based on views that you create during multi-mode multi-corner analysis. By arranging the timing information of different views quickly, the command helps in analyzing timing paths.

The command can be applied wherever the user loads the machine readable timing report.

## Parameters

|                                        |                                                                                                                                                                                                                                                                                       |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                                  | Outputs a brief description that includes type and default information for each <code>analyze_paths_by_view</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br><code>man analyze_paths_by_view</code> |
| -master<br><i>master_category_name</i> | Specifies that the timing paths should be categorized only for the specified master category.                                                                                                                                                                                         |
| -prefix <i>string</i>                  | Adds a prefix to the category name.                                                                                                                                                                                                                                                   |

## Examples:

The following command categorizes paths based on views that you created during mmmc analysis :

```
analyze_paths_by_view
```

## Related Commands

- `create_path_category`
- `delete_path_category`

# create\_histogram\_png

```
create_histogram_png
[-help]
[-height integer]
-name string
[-width integer]
```

Dumps out the timing histogram image from global timing debug in the PNG format without bringing up the GUI. Earlier, this was done when the GUI was displayed by right-clicking the histogram window and selecting Snapshot. But that worked only when the snapshot was displayed in the GUI. This command has eliminated the necessity of bringing up the GUI to dump out the timing histogram.

## Parameters

|                        |                                                                                                                                                                                                                                                                                      |

[-uncertainty string]
[-view string]
```

This command creates path categories using conditions for grouping paths according to analyzed timing results. The command can be applied wherever the user loads the machine readable timing report.

## Parameters

|                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <code>-delay_of_every_net float</code>                              | Indicates that the delay of every instance in the design matches the specified <i>float</i> value.                                                |
| <code>-delay_of_any_inst_of_lib_cell float</code>                   | Indicates that the delay of any instance in the specified library cell matches the specified <i>float</i> value.                                  |
| <code>-delay_of_any_inst_of_name<br/>string_plus_float</code>       | Indicates that the delay of any instance in the design matching the specified name matches the specified <i>float</i> value.                      |
| <code>-delay_of_any_inst_not_of_name<br/>string_plus_float</code>   | Indicates that the delay of any instance in the design not matching the specified name matches the specified <i>float</i> value.                  |
| <code>-delay_of_any_net_of_name<br/>string_plus_float</code>        | Indicates that the delay of any net in the design matching the specified name matches the specified <i>float</i> value.                           |

|                                                                     |                                                                                                                                    |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>-delay_of_any_net_not_of_name<br/>string_plus_float</code>    | Indicates that the delay of any net in the design not matching the specified name matches the specified <i>float</i> value.        |
| <code>-delay_of_every_inst_of_name<br/>string_plus_float</code>     | Indicates that the delay of every instance in the design matching the specified name matches the specified <i>float</i> value.     |
| <code>-delay_of_every_inst_of_lib_cell string</code>                | Indicates that the delay of every instance in the design matching the specified name matches the specified <i>float</i> value.     |
| <code>-delay_of_every_inst_not_of_name<br/>string_plus_float</code> | Indicates that the delay of every instance in the design not matching the specified name matches the specified <i>float</i> value. |
| <code>-delay_of_every_net_of_name<br/>string_plus_float</code>      | Indicates that the delay of every net in the design matching the specified name matches the specified <i>float</i> value.          |
| <code>-delay_of_every_net_not_of_name<br/>string_plus_float</code>  | Indicates that the delay of every net in the design not matching the specified name matches the specified <i>float</i> value.      |
| <code>-view</code>                                                  | <i>Type:</i> String, optional                                                                                                      |

## Examples:

- The following command categorizes paths whose source clock is `vclk1`:  

```
create_path_category -name vclk1 -from_clock vclk1
```

The category `vclk1` is created.
- The following command categorizes paths whose skew is larger than 0.2:  

```
create_path_category -name worst_skew -skew {> 0.2}
```

The category `worst_skew` is created.

## Related Commands

[create\\_path\\_category](#)

# delete\_path\_category

```
delete_path_category
[-help]
category_name
```

Deletes the selected category name.  
The command can be applied when categories are created in Global Timing Debug.

## Parameter

|               |                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help         | Outputs a brief description that includes type and default information for each delete_path_category parameter.<br><br>For a detailed description of the command and all of its parameters, use the man command:<br>man delete_path_category |
| category_name | Specifies the name of the category to be deleted.                                                                                                                                                                                            |

## Examples:

The following command deletes the category worst\_paths:  
delete\_path\_category worst\_paths

## Related Commands

create\_path\_category

# gui\_gtd\_highlight\_timing\_report

```
gui_gtd_highlight_timing_report
[-help]
[-append]
[-color_index integer]
[-in_file filename]
[-no_arrow]
[-paths path_number | -all]
```

Highlight the selected paths in the user interface.

## Parameter

|                                 |                                                                                                                                                                                                                                                                                                          |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                           | Outputs a brief description that includes type and default information for each <code>gui_gtd_highlight_timing_report</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br><code>man gui_gtd_ighlight_timing_report</code> |
| -all                            | Highlights all the paths. The option is of type boolean and required.                                                                                                                                                                                                                                    |
| -append                         | Appends a path to the current highlight.                                                                                                                                                                                                                                                                 |
| -<br>color_index <i>integer</i> | Specifies the <code>color_index</code> of the path from 1 to 8. The option is of type int and optional with minimum value 1, and maximum value 8.                                                                                                                                                        |
| -in_file <i>filename</i>        | Name of the file. The option is of type string and optional.                                                                                                                                                                                                                                             |
| -no_arrow                       | Removes the highlighted arrow. The option is of type boolean and optional.                                                                                                                                                                                                                               |
| -paths <i>path_number</i>       | Specifies the number of the path. The option is of type string and required.                                                                                                                                                                                                                             |

## Related Commands

[gui\\_highlight\\_pin\\_connection](#)

# gui\_open\_gtd

gui\_open\_gtd  
[-help]

Opens the global timing debugger in the common user interface mode for accessing the GTD files report.

## Parameters

|           |                                                                                                                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -<br>help | Outputs a brief description that includes the type and default information for each <code>gui_open_gtd</code> parameter.<br><br>For a detailed description of the command and all its parameters, use the <code>man</code> command:<br><code>man gui_open_gtd</code> |

# load\_failure\_report

```
load_failure_report
[-help]
-file filename
```

Loads the failure report generated during `opt_signoff`. This failure report contains various reasons that limited timing closure during automated signoff ECO. This command reads the Failure Catalog File (FCF) in the format used by the Failure Catalog Browser (FCB).

## Parameters

|                                         |                                                                                                                                                                                                                                                                                    |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                      | Outputs a brief description that includes the type and default information for each <code>load_failure_report</code> parameter.<br><br>For a detailed description of the command and all its parameters, use the <code>man</code> command:<br><code>man load_failure_report</code> |
| <code>-<br/>file <i>filename</i></code> | Specifies the name of the file describing the failure category. This is a mandatory parameter.                                                                                                                                                                                     |

## Related Commands

`opt_signoff`

# read\_path\_categories

```
read_path_categories
[-help]
in_file filename
```

Loads the path category file in the Timing Debug form. The path category file contains category definitions that you saved in an earlier timing debug analysis. To save path categories, use the `write_path_categories` command.

## Parameter

|                                         |                                                                                                                                                                                                                                                                                             |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                      | <p>Outputs a brief description that includes type and default information for each <code>read_path_categories</code> parameter.</p> <p>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br/><code>man read_path_categories</code></p> |
| <code>in_file</code><br><i>filename</i> | <p>Specifies the name of the category file.</p>                                                                                                                                                                                                                                             |

## Example

The following command loads the path category file `category.cat`:

```
read_path_categories in_file category.cat
```

## Related Commands

[write\\_path\\_categories](#)

# read\_timing\_debug\_report

```
read_timing_debug_report
[-help]
[-name report_name]
[{-proto [-slack_margin number] [-num_path number]}]
[-num_path]
timing_report_filename
```

Loads the violation report in Tempus for debugging timing results.

 The violation report that you specify using the `read_timing_debug_report` command is in the output binary format, which you can generate through the `binary` value of the `report_timing -output_format` command parameter.

**Note:** The violation report that you specify in this command has a special machine readable format. Use the `report_timing -output_format gtd` command to generate the machine readable violation report.

## Parameter

|                                                                  |                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                               | <p>Outputs a brief description that includes type and default information for each <code>read_timing_debug_report</code> parameter.</p> <p>For a detailed description of the command and all of its parameters, use the <code>man</code> command:</p> <pre>man read_timing_debug_report</pre>                                                                                     |
| <code>timing_report_filename</code>                              | Specifies the name of the timing debug <code>timing_report_file</code> .                                                                                                                                                                                                                                                                                                          |
| <code>-name</code>                                               | Specifies the report name to load the machine readable timing report <code>timing_report_files</code> incrementally.                                                                                                                                                                                                                                                              |
| <code>-num_path</code>                                           | Specifies the number of paths to be reported in the detailed path violations.                                                                                                                                                                                                                                                                                                     |
| <code>{-proto [-slack_margin number]  [-num_path number]}</code> |                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                                  | <p>Creates flex model categories and displays the top path of the top 8 (by default) categories. This option can be used for design that has flexModels.</p> <p>Use <code>-additional_slack_past_wns</code> to report all paths with slack worst than (WNS and additional specified slack value).</p> <p>Use <code>-num_path</code> to control the number of violation paths.</p> |

## Examples:

- The following command loads the machine readable timing report `top.btarpt`:  
`read_timing_debug_report top.btarpt`
- The following commands load two machine readable timing reports `top1.btarpt` and `top2.btarpt` together:

```
read_timing_debug_report -name default_report top1.btarpt
```

```
read_timing_debug_report -name default_report top2.btarpt
```

GTD will first load the report `top1.btarpt`, then append `top2.btarpt` incrementally to the current report.

**Note:** The `name` can be specified by user with any string, it is not the `timing_report_file` name.

## Related Commands

[report\\_timing](#)

## write\_category\_summary

```
write_category_summary
[-help]
out_file string
[[-sort_low_to_high | -sort_high_to_low]
[-sort_by_tns | -sort_by_wns]]
[-csv | {-no_frame_fix_width [-no_split]}]
```

Writes a text file containing the following information:

- Category name
- Total number of paths
- Number of passing paths
- Number of failing paths
- Worst negative slack
- Total negative slack

## Parameters

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>               | <p>Outputs a brief description that includes type and default information for each <code>write_category_summary</code> parameter.</p> <p>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br/> <code>man write_category_summary</code></p>                                                                                                                                                                                                                                                       |
| <code>-sort_low_to_high</code>   | Specifies that the report in ascending order, should specify option <code>-sort_by_tns</code> <b>or</b> <code>-sort_by_wns</code> .                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-sort_by_tns</code>        | The TNS value specified by the sorting key through the option <code>-sort_low_to_high</code> <b>or</b> <code>-sort_high_to_low</code> .                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-sort_by_wns</code>        | The WNS value specified by the sorting key through the option <code>-sort_low_to_high</code> <b>or</b> <code>-sort_high_to_low</code> .                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-csv</code>                | Reports entries in csv format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-sort_high_to_low</code>   | Specifies that the report in descending order, should specify option <code>-sort_by_tns</code> <b>or</b> <code>-sort_by_wns</code> .                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-no_frame_fix_width</code> | <p>Specifies that the table columns have a fixed minimum width, but no maximum width (the data does not wrap). Column data that fits within the column's minimum width will left-justify and pad its location to fill the specified column space.</p> <p>Column data that is longer than the column's minimum width will take as much space in the table as needed. If a column is overwritten by the data from the preceding column, its data will begin on a new line at the correct column location.</p> <p><i>Default:</i> <code>-frame</code></p> |
| <code>-no_split</code>           | <p>Specifies that each column follows the preceding column without splitting to a new line, if the data in one column overruns the next column. The wrapping behavior for data is controlled by the size of the display window.</p> <p>This format is useful for machine parsing the report.</p> <p><b>Note:</b> You must specify <code>-no_frame_fix_width</code> in order to use this parameter.</p>                                                                                                                                                 |
| <code>out_file fileName</code>   | <p>Specifies the name of the category report file.</p> <p><i>Default:</i> <code>category.rpt</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Examples

The following command writes a category summary file `category.rpt`:

```
write_category_summary out_file category.rpt
```

# write\_histogram\_view

```
write_histogram_view
[-help]
file_name string
[-type string]
```

Saves (dumps) the image of the histogram shown in *Global Timing Debug* automatically during the process.

## Parameters

|                         |                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                   | Outputs a brief description that includes type and default information for each <code>write_histogram_view</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br><code>man write_histogram_view</code> . |
| file_name <i>string</i> | Specifies the name of the image file to save the histogram.                                                                                                                                                                                                                           |
| -type <i>string</i>     | Specifies the type of file (image format) to be saved. Options are <code>bmp/jpg/gif/tif/csv</code> .<br><br><i>Default:</i> <code>bmp</code>                                                                                                                                         |

# write\_path\_categories

```
write_path_categories
[-help]
out_file filename
```

Saves the selected categories in a path category file. You can use the category file to load saved category definitions in a new timing debug session. To load the saved category definitions, use the [read\\_path\\_categories](#) command.

## Parameters

|                                          |                                                                                                                                                                                                                                                                                       |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                       | Outputs a brief description that includes type and default information for each <code>write_path_categories</code> parameter.<br><br>For a detailed description of the command and all of its parameters, use the <code>man</code> command:<br><code>man write_path_categories</code> |
| <code>out_file</code><br><i>filename</i> | Specifies the name of the category file.                                                                                                                                                                                                                                              |

## Example

The following command saves the path category file `category.cat`:

```
write_path_categories out_file category.cat
```

## Related Commands

[read\\_path\\_categories](#)

# write\_path\_list\_summary

```
write_path_list_summary
[-help]
[-category string]
[-compress]
[-csv]
-report fileName
```

Writes the Path List categorized summary into a text and/or CSV file.

## Parameters

|                             |                                                                                                                                                                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                       | Outputs a brief description that includes the type and default information for each <code>write_path_list_summary</code> parameter.<br><br>For a detailed description of the command and all its parameters, use the <code>man</code> command:<br><code>man write_path_list_summary</code> |

| -report<br><i>fileName</i>  | Specifies the name of the CSV output file.                                                                                                                                                                                                                                                 |

## write\_text\_timing\_report

```
write_text_timing_report
[-help]
[-machine_readable file.mtarpt |
-category category_name]
[-format{{column1 width1} {column2 width2} ...}]
[-path_spec path_specification]
[-summary] |
report_file file.tarpt
```

Writes a text file containing information about paths that have been loaded from a `.mtarpt` file from Timing Debug, either with the `read_timing_debug_report` command or in the *Display/Generate Timing Report* form in the GUI.

Paths are selected as follows:

- If only one `.mtarpt` file is loaded and no other parameters are specified, then the tool writes all the paths contained in the loaded `.mtarpt` file.
- If there are several `.mtarpt` files loaded, you must specify the `.mtarpt` file from which the tool can select the paths, except if a category is specified.

You can use this report for performing timing analysis.

If only one machine-readable report file is loaded, then the tool writes all paths from that file into the output report. If more than one file is loaded, then the tool issues an error message.

**Note:** The generated report cannot be read back into the timing debug environment.

## Parameters

|                                                                           |                                                                                                                                                                                                                                                                                                     |

|                                                                           | <p>Writes a single number or path range separated by blank space. A path range is two numbers separated by a minus "-" sign. You can use this parameter only if a single file is specified or loaded.</p>                                                                                           |
| <code>report_file <i>file.tarpt</i></code>                                |                                                                                                                                                                                                                                                                                                     |
|                                                                           | <p>Specifies the name of the text output file.</p>                                                                                                                                                                                                                                                  |
| <code>-summary</code>                                                     | <p>Writes the file header only. Use this parameter if you do not need a detailed table.</p>                                                                                                                                                                                                         |

## Examples

- The following command loads machine-readable report `top.mtarpt`:  
`load_timing_debug_report top.mtarpt`
- The following command reads the `top.mtarpt` report and reports paths 1 through 50 in the `top_tarpt.txt` file.  
`write_text_timing_report -machine_readable top.mtarpt -path_spec {1-50} report_file top_tarpt.txt`

## Related Commands

`read_timing_debug_report`

# zoom\_highlighted\_timing\_path

```
zoom_highlighted_timing_path
[-help]
[-previous | -next]
```

Enables zooming into highlighted timing paths within the Timing Debug form in the Layout view, and supports sequential traversal when multiple paths are highlighted. This command reduces the number of steps required to view and navigate timing paths in the Layout view. The command is very useful for zooming into highlighted timing paths in large designs.

## Parameters

|           |                                                                                                                                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# Timing Modeling Commands

---

- [Extracted Timing Model - ETM](#)
- [Prototype Timing Model - PTM](#)

## Extracted Timing Model - ETM

- [check\\_timing\\_model](#)
- [merge\\_model\\_timing](#)
- [report\\_timing\\_model](#)
- [write\\_timing\\_model](#)

# check\_timing\_model

```
check_timing_model
[-absolute_cap_tolerance float]
[-absolute_tolerance float]
[-absolute_tolerance_optimistic float]
[-absolute_tolerance_pessimistic float]
[-absolute_transition_tolerance float]
-compare_file string
[-ignore_view]
-out_file string
[-percentage_cap_tolerance float]
[-percentage_tolerance float]
[-percentage_tolerance_optimistic float]
[-percentage_tolerance_pessimistic float]
[-percentage_transition_tolerance float]
-reference_file string
```

Compares two reports that contain interface timing characteristics generated by the `report_timing_model` command.

This command compares the interface timing report generated by using the `report_timing_model` command on the original netlist with the interface timing report generated by using the `report_timing_model` command on the model extracted for the same design.

## Parameters

| <code>-percentage_cap_tolerance value</code> | <p>Specifies the tolerance value for capacitance (as a percentage) while comparing two report files. This parameter specifies the permissible difference, in percentage, between the capacitance values of two report files. If the percentage difference in the value of capacitance exceeds the percentage tolerance value specified, the comparison status is set to <code>FAIL</code>.</p> <p><b>Note:</b> When this parameter is not specified, the software uses the percentage value specified with the <code>-percentage_tolerance</code> parameter. If the <code>-percentage_tolerance</code> parameter is not specified, the value defaults to 0.</p> <div>  When the <code>-percentage_cap_tolerance</code> and <code>-absolute_cap_tolerance</code> parameters are used together, the comparison status is set to <code>FAIL</code> only when the difference in the value of capacitance exceeds the specified absolute as well as percentage tolerance values. </div> |
| <code>-percentage_tolerance float</code>     | <p>Specifies the percentage tolerance value for comparing the timing data of two report files. The percentage tolerance value is used when there is a difference between the timing characteristics of the reference file (<code>-reference_file</code>) and the file that is being compared (<code>-compare_file</code>) to determine the <code>PASS</code> or <code>FAIL</code> status of the comparison. If the percentage difference in the value of a timing characteristic exceeds the percentage tolerance value, the comparison status is set to <code>FAIL</code>.</p> <p><b>Note:</b> When used with the <code>-absolute_tolerance</code> option, the difference in the value of a timing characteristic should exceed both percentage and absolute tolerance values for the comparison result status of an arc to be <code>FAIL</code>.</p> <p><i>Default:</i> 0</p>                                                                                                                                                                                     |

|                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <p><code>-percentage_transition_tolerance</code><br/><i>float</i></p>  | <p>Specifies the tolerance value for transition time at ports (as a percentage) while comparing two report files. This parameter specifies the permissible difference, in percentage, between the transition time at ports of two report files. If the percentage difference in the transition time exceeds the percentage tolerance value specified, the comparison status is set to <code>FAIL</code>.</p> <p><b>Note:</b> When this parameter is not specified, the software uses the percentage value specified with the <code>-percentage_tolerance</code> parameter. If the <code>-percentage_tolerance</code> parameter is not specified, the value defaults to 0.</p> <div data-bbox="646 1167 1505 1430"> <p> When the <code>-percentage_transition_tolerance</code> and <code>-absolute_transition_tolerance</code> parameters are used together, the comparison status is set to <code>FAIL</code> only when the difference in the value of transition exceeds the specified absolute as well as percentage tolerance values.</p> </div> |
| <p><code>-reference_file</code> <i>string</i></p>                      | <p>Specifies the name of the reference file that is used for comparison. This is the report file that was generated by using the <code>write_timing_model</code> command on the original design.</p> <p>The file specified with the <code>-compare_file</code> option is compared with this file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Examples

- The following command compares the timing characteristics of the `sample_compare.rpt` file with the `sample_reference.rpt` file and generates the comparison results in the `sample_output.rpt` file:

```
tempus > check_timing_model -reference_file sample_reference.rpt -compare_file
sample_compare.rpt
-out_file sample_output.rpt
```

```

## merge\_model\_timing

```
merge_model_timing
[-help]
-input_library_file string
[-keep_separate_arc]
[-merged_library_file string]
-mode_group string
-modes string
[-pin_cap_tolerance float]
[-tolerance float]
```

Merges extracted timing models (ETM) for various analysis views into a single output.

The `merge_model_timing` command should be the last command in the run script. Also, this command should be run separately in a Tempus session when a design is not loaded.

When the DRV values are different in the libraries that are merged, then Tempus saves the worst value of the DRV with a warning message.

If the DRV values are not equal, the greater value is stored for the following:

- Minimum transition
- Minimum capacitance
- Minimum fanout

The smaller value is stored for the following, in case of unequal DRVs:

- Maximum transition
- Maximum capacitance
- Maximum fanout
- Fanout load

## Parameters

|                                                    |                                                                                                                                         |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>-keep_separate_arc</code>                    | Enables creating separate timing arcs with respective modes.                                                                            |
| <code>-input_library_file</code><br><i>string</i>  | Specifies input library files that are to be merged.                                                                                    |
| <code>-modes</code> <i>string</i>                  | Specifies the mode names required for merging the libraries. The number of mode names should be equal to the number of input libraries. |
| <code>-mode_group</code> <i>string</i>             | Specifies the name of the mode group.                                                                                                   |
| <code>-merged_library_file</code><br><i>string</i> | Specifies the name of the merged library output file name. By default, the output file name is <code>merge.lib</code> .                 |
| <code>-pin_cap_tolerance</code> <i>float</i>       | Specifies the pin capacitance tolerance for making tolerance comparison for library merging.                                            |
| <code>-tolerance</code> <i>float</i>               | Specifies the tolerance value for making tolerance comparison for library merging.                                                      |

## Examples

- The following command merges library files `modell.view1.lib` and `modell.view1.lib.ref` into a single output file:  

```
tempus > merge_model_timing -input_library_file "modell.view1.lib modell.view1.lib.ref"
-modes "v1 v2" -mode_group v1_v2
```

## Related Topics

- See "[Extracted Timing Models](#)" in the *Tempus User Guide*.

## Related Commands

- `write_timing_model`

## report\_timing\_model

```
report_timing_model
[-help]
model_timing_report_file
[-in_ports string]
[-nworst integer]
[-out_ports string]
[-slew_propagation {worst | path_based}]
[-type {arc | slack}]
[-verbose]
[-view string]
-setup string | -hold string
```

Writes the interface timing characteristics of the design in the specified timing model report file.

The report file contains the following sections:

- **Worst-Case Arc/Slack:** Contains details about the extracted arcs and the slack or delay across them depending on the argument specified with the `-type` option.
- **Transition Time:** Contains information about transition time at ports.
- **Capacitance:** Contains the capacitance values for the ports.
- **Design Rules:** Contains the design rules applied to the ports.

The command reports unconstrained arcs delays by default.

## Parameters

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>-help</code>                                  | Outputs a brief description that includes type and default information for each <code>report_timing_model</code> parameter. For a detailed description of the command and all of its parameters, use the man command: <code>man report_timing_model</code> .                                                                                                                                                                    |
| <code>-hold string</code>                           | Writes the paths corresponding to early analysis.                                                                                                                                                                                                                                                                                                                                                                               |
| <code>model_timing_report_file</code>               | Specifies the name of the interface timing model report file that will be generated with the interface timing characteristics of the loaded design.                                                                                                                                                                                                                                                                             |
| <code>-in_ports string</code>                       | Restricts the <code>report_timing_model</code> report to the input ports specified with this parameter. As a result, the software considers the timing paths related to the specified input ports only, while generating the report.<br><br>If this parameter is not specified, all the input ports in the design are considered while generating the report.                                                                   |
| <code>-nworst integer</code>                        | Specifies the number of paths to be enumerated for each end point.<br><br><b>Note:</b> The extracted model will contain greater number of setup/hold paths per end point because it will have lesser end points compared to the original netlist. Therefore, it is recommended that you use a greater <code>-nworst</code> value such as 40 while writing a timing report for the extracted model to derive better correlation. |
| <code>-out_ports string</code>                      | Restricts the <code>report_timing_model</code> report to the output ports specified with this parameter. As a result, the software considers the timing paths related to the specified output ports only, while generating the report.<br><br>If this parameter is not specified, all the output ports in the design are considered while generating the report.                                                                |
| <code>-setup string</code>                          | Writes the paths corresponding to late analysis.                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-slew_propagation {worst   path_based}</code> | Sets the slew propagation mode to use for dumping the timing characteristics of the design.                                                                                                                                                                                                                                                                                                                                     |
| <code>-type {arc   slack}</code>                    | Determines whether to report arc delay values ( <code>arc</code> ) or the worst-slack values ( <code>slack</code> ).                                                                                                                                                                                                                                                                                                            |
| <code>-verbose</code>                               | Prints the command progress details.                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-view string</code>                           | Specifies a view name. The report can be generated for a specific view.                                                                                                                                                                                                                                                                                                                                                         |

## Examples

- The following command generates a detailed report of the worst-slack values for the specified view:

```
tempus > report_timing_model rep2.lib -verbose -type slack -view FN_2max
Section 1 : Worst Case Slacks
Analysis Mode : setup
Description : worst case slacks
#
From To Arc Type Transition Slack View

BTN_clk wrf2_clk_o max_sequential_uncons_arrival fall/fall 9.615
FN_2max
BTN_clk wrf2_clk_o max_sequential_uncons_arrival rise/rise 0.000
FN_2max
dvWe_GI gci_aon_clk setup fall/rise 38.838
FN_2max
dvWe_GI gci_aon_clk setup rise/rise 37.977
FN_2max
m_PBG {wl_gpio_out_por[0]} max_sequential_uncons_arrival rise/fall 6.767
FN_2max

```

- The following command generates a detailed report of the arc delay values for the specified view:

```
tempus > report_timing_model rep3.lib -verbose -type arc -view FN_2max

Section 1 : Worst Case Arcs
Analysis Mode : setup
Description : worst case arcs
#
From To Arc Type Transition Arc-Delays View

Section 2 : Transition time
Analysis Mode : setup
Description : Actual transition times on the ports
View : FN_2max
#
Port RiseTran FallTran
```

```

RF_TI2G_GP 0.0040 0.0040
RF_TI5G 0.0040 0.0040
mux_ft_v 0.0040 0.0040
dvadr_GI[10] 0.0040 0.0040
dvadr_GI[9] 0.0040 0.0040
dvadr_GI[8] 0.0040 0.0040
dvadr_GI[7] 0.0040 0.0040
dvadr_GI[6] 0.0040 0.0040
```

- The following command extracts the interface timing characteristics of the currently loaded design and writes out the report file named `sample.rpt` with the arc delay information:

```
tempus > report_timing_model -type arc sample.rpt
```

```

Section 1 : Worst Case Arc
Analysis Mode : setup
Description : worst case arcs
#
From To Arc Type Transition Arc-Delays

in CLK3 setup fall/rise 0.134
in CLK3 setup rise/rise -0.005

Section 2 : Transition time
Analysis Mode : setup
Description : Actual transition times on the ports
#
Port RiseTran FallTran

in 0.000 0.000
clk 0.000 0.000

A pessimistic path violating percentage as well as absolute tolerance limit will be flagged as FAIL in the <code>check_timing_model</code> command output report.</p> <p>You can use this parameter when the <code>-validation_dir</code> is used with model extraction.</p> <p><i>Default:</i> 3%</p> |
| <code>-post_check</code>                                     | Checks the generated ETM library using Valus.                                                                                                                                                                                                                                                                                                                                          |
| <code>-precision integer</code>                              | Specifies the floating point precision used for the timing model                                                                                                                                                                                                                                                                                                                       |
| <code>-resolution float</code>                               | Specifies the magnitude of delay difference that can be ignored in extraction                                                                                                                                                                                                                                                                                                          |
| <code>-tolerance float</code>                                | Specifies the accuracy level of extractor in percent                                                                                                                                                                                                                                                                                                                                   |
| <code>-validation_dir &lt;string&gt;</code>                  | <p>Enables the validation of generated ETM for corresponding view and displays number of failures at the end of validation. It is mandatory to specify the name of validation directory with this option (<code>-validation_dir valDir</code>), this contains the <code>write_model_timing</code>, <code>check_timing_model</code> and summary reports.</p>                            |
| <code>-verilog_shell_file filename</code>                    | Generates a Verilog shell file that instantiates the timing model                                                                                                                                                                                                                                                                                                                      |
| <code>-verilog_shell_module top_module_name</code>           | Specifies the top module name of the Verilog shell file.                                                                                                                                                                                                                                                                                                                               |
| <code>-view string</code>                                    | Specifies the view for which model needs to be extracted.                                                                                                                                                                                                                                                                                                                              |

## Examples

- The following command builds a `.lib` model (`block.lib`) for the block:  

```
tempus > write_timing_model block.lib
```
- The following command creates the timing model for the `tst_model` cell belonging to the `tst_lib` library, and writes the model into the `tst.lib` liberty file:  

```
tempus > write_timing_model -cell_name tst_model -lib_name tst_lib tst.lib
```

- The following command validates the generated ETM, where the pessimistic and optimistic path violation tolerance is set to 1%:

```
write_timing_model tst.lib -cell_name block_1 -validation_dir -
percent_tolerance_validation 1 -percent_tolerance_optimistic_validation 1
 \ -percent_tolerance_pessimistic_validation 1
```

- The following command includes details related to the power ground (of the pins) and power consumed by a block:

```
write_timing_model tst.lib -cell_name block_1 -include_power -include_power_ground
```

## create\_ptm\_constraint\_arc

```
create_ptm_constraint_arc
-setup
-hold
-from clock_port_name]
[-to port_name]
-edge { rise | fall }
-path_type pathTypeName
- path_factor value
[-value constraint_value]
```

Sets the timing check from the clock input port to the data input port.

To create a new timing check arc which does not already exist in the timing model, the clock port that you specify as `-from` should be created as a clock type by the `create_ptm_port` command.

**Note:** The `create_ptm_constraint_arc` command can be specified only after you create a PTM model using the `create_ptm_model` command.

### Parameters

|                                      |                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-edge { rise   fall }</code>   | Specifies which transition on the clock input is relevant for the timing check arc definition.                                                                                                                                                                                                                               |
| <code>-from clock_port_name</code>   | Specifies the name of the clock port, which can be an input, bidirectional, or internal port.<br><b>Note:</b> This parameter allows you to specify a pattern for port names using wildcard characters.                                                                                                                       |
| <code>-hold</code>                   | Specifies that the check arc to be created is of <code>hold</code> type.                                                                                                                                                                                                                                                     |
| <code>-path_type pathTypeName</code> | Specifies the reference time arc created using the <code>create_ptm_path_type</code> command. This parameter is mutually exclusive to the <code>-value</code> parameter currently available. Either the <code>-value</code> parameter or the <code>-path_type</code> parameter must be specified.                            |
| <code>-path_factor value</code>      | Used as an additional scaling value for the delay/slew tables.<br><i>Default:</i> 1.0                                                                                                                                                                                                                                        |
| <code>-setup</code>                  | Specifies that the check arc to be created is of <code>setup</code> type.                                                                                                                                                                                                                                                    |
| <code>-to port_name</code>           | Specifies the name of the input or bidirectional port which will be the signal pin for check arc. If you do not specify a port name, the software sets the timing check for all input and bidirectional data ports.<br><b>Note:</b> This parameter allows you to specify a pattern for port names using wildcard characters. |

|                                                      |                                         |
|------------------------------------------------------|-----------------------------------------|
| <code>-value</code><br><code>constraint_value</code> | Specifies a value for the timing check. |
|------------------------------------------------------|-----------------------------------------|

## Example

- The following command sets the setup timing check value of 0.3 with respect to rising edge at the clock port `clock_in` to the data input port `data_in`:

```
tempus> create_ptm_constraint_arc -setup -value 0.3 -from clock_in -to data_in -edge
rise
```

- The following command specifies the reference check arc by specifying the path type as `SETUP_TYPE1` and path factor as 1.03:

```
tempus> create_ptm_constraint_arc -from clock_gen_1 -to data_in -path_type SETUP_TYPE1 -
path_factor 1.03
```

## Related Commands

- `create_ptm_port`

## create\_ptm\_delay\_arc

```
create_ptm_delay_arc
-from port_name
-path_type pathTypeName
-path_factor value
-to port_name
[-edge { rise | fall }]
-value delay_value
```

Sets the delay for combinational or sequential paths from input ports to the output ports. If you do not specify the drive type on the output port, a constant timing table is created. In a constant timing table, delay is constant. It does not vary with respect to input slew and output capacitance.

To create a new sequential timing arc which does not already exist in the timing model, the port you specify as `-from` should be created as a clock type by the `create_ptm_port` command.

**Note:** The `create_ptm_delay_arc` command can be specified only after you create a PTM model using the `create_ptm_model` command.

### Parameters

|                                      |                                                                                                                                                                                                                                                                               |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-edge rise   fall</code>       | Specifies the edge on the clock input relevant to the sequential delay arc definition. By default, the software uses a rising clock transition.                                                                                                                               |
| <code>-from port_name</code>         | Specifies the name of the input port or the clock port.<br><b>Note:</b> This parameter allows you to specify a pattern for port names using wildcard characters.                                                                                                              |
| <code>-path_type pathTypeName</code> | Specifies the reference time arc created using the <code>create_ptm_path_type</code> command. This parameter is mutually exclusive to the <code>-value</code> parameter. Either the <code>-value</code> parameter or the <code>-path_type</code> parameter must be specified. |
| <code>-path_factor value</code>      | Used as an additional scaling value for the delay/slew tables.<br><i>Default:</i> 1.0                                                                                                                                                                                         |
| <code>-to port_name</code>           | Specifies the name of the output port or the bidirectional port.<br><b>Note:</b> This parameter allows you to specify a pattern for port names using wildcard characters.                                                                                                     |
| <code>-value delay_value</code>      | Specifies the value for the delay.                                                                                                                                                                                                                                            |

## Example

- The following command defines a sequential delay arc with respect to the rising edge at the clock port `clock_in` to the output port `data_out` and specifies the delay value as 1.0:

```
tempus> create_ptm_delay_arc -from clock_in -to data_out -edge rise -value 1.0
```

- The following command specifies the reference check arc by specifying the path type as `SETUP_TYPE1` and path factor as 1.03:

```
tempus> create_ptm_path_type SEQ_TYPE -type sequential -lib_cell DFFHQX1 -relative_pin
CK -target_pin Q
```

```
tempus> create_ptm_delay_arc -from ptm_clk -to ptm_reg_out -path_type SEQ_TYPE
```

## Related Commands

- `create_ptm_port`

## create\_ptm\_drive\_type

```
create_ptm_drive_type
-lib_cell cell_name
[-input_slew_fall value]
[-input_slew_rise value]
[-input_pin pin_name]
[-output_pin pin_name]
drive_type_name
```

Creates drive types to specify the drive strength equivalent to existing library cells. Optionally, you can also specify the rise or fall transition value(s) at the driver port using this command.

This command can be specified only after you create a PTM model using the `create_ptm_model` command.

**Note:** Use the `set_ptm_port_drive` command to associate the drive type to existing ports.

### Parameters

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>drive_type_name</i>        | Specifies the name of the drive type to use for the timing model.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>-lib_cell cell_name</i>    | Specifies the reference cell which will be used to determine the drive value.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>-input_pin pin_name</i>    | <p>Specifies the input pin of the timing arc for the reference cell specified with the <code>-lib_cell</code> parameter. The combinational arcs starting from this pin will be used to create the drive type.</p> <p>When only one of <code>-input_pin/-output_pin</code> parameter is specified, the tool chooses the first random combinational arc at the specified pin.</p> <p>When none of these options are specified, the tool chooses the first random combinational arc.</p> |
| <i>-input_slew_fall value</i> | Specifies the fall transition value.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>-input_slew_rise value</i> | Specifies the rise transition value.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-output_pin</code><br><i>pin_name</i> | <p>Specifies the output pin of the timing arc for the reference cell specified with the <code>-lib_cell</code> option. The combinational arcs ending to this pin will be used to create the drive type.</p> <p>When only one of <code>-input_pin/-output_pin</code> parameter is specified, the tool chooses the first random combinational arc at the specified pin.</p> <p>When none of these options are specified, the tool chooses the first random combinational arc.</p> |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

- The following command defines the drive type name as `stdDrive` with drive resistance of library cell `INVX1`:

```
tempus> create_ptm_drive_type -lib_cell INVX1 stdDrive
```

- The following command defines the drive type name as `stdDrive` with drive resistance of the library cell `BUF1`, and input and output pins as `B` and `Y`, respectively:

```
tempus> create_ptm_drive_type -lib_cell BUF1 -input_pin B -output_pin Y stdDrive
```

## Related Commands

- `create_ptm_model`
- `set_ptm_port_drive`

## create\_ptm\_generated\_clock

```
create_ptm_generated_clock
-source clock_pin
[-divide_by value | -multiply_by value]
clock_name
```

Creates an internal pin on a timing model or uses an existing internal pin (defined by the `create_ptm_port` command), and creates a generated clock on this internal pin.

The following points apply to the usage of this command:

- The internal pin created with this command will be treated as a clock port. This internal pin can, therefore, be used to create timing check arcs using the `create_ptm_constraint_arc` command and sequential delay arcs using the `create_ptm_delay_arc` command.
- The latency of the generated clock is set to 0.
- Any timing arc related to the internal pin must include the clock latencies defined on both: the internal pin and the master pin.
- The generated clock appears in the timing model generated by the `save_ptm_model` command.
- The internal pin and the generated clock are persistent, that is, they cannot be deleted using PTM commands.

### Parameters

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>clock_name</code>                            | Specifies the name of the generated clock defined on the internal pin.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-divide_by value   -multiply_by value</code> | <p>Specifies the frequency division or multiplication factor.</p> <p>When you use the <code>-divide_by</code> option, the generated clock period is equal to the master clock period multiplied by the value specified with the <code>-divide_by</code> option. For example, if the value is 2, the generated clock period is two times the master clock period.</p> <p>When you use the <code>-multiply_by</code> option, the generated clock period is equal to the master clock period divided by the value specified with the <code>-multiply_by</code> option. For example, if the value is 3, the generated clock period is one-third the master clock period.</p> |
| <code>-source clock_pin</code>                     | <p>Specifies the source from which the derived clock is generated.</p> <p>The source can be an existing clock port or the one created by using the <code>create_ptm_port</code> command, and a clock should be available on this port.</p> <p>This clock port is set at the master pin for the generated clock.</p>                                                                                                                                                                                                                                                                                                                                                      |

## Example

- The following command creates a generated clock with the name `clock_gen` on internal pin `clock_gen` (also create the pin if it does not already exist), using the clock port `clock_in` as source pin for the generated clock, and the frequency division factor of 2:

```
tempus> create_ptm_generated_clock -source clock_in -divide_by 2 clock_gen
```

## Related Commands

- `create_ptm_constraint_arc`
- `create_ptm_delay_arc`

## create\_ptm\_load\_type

```
create_ptm_load_type
-lib_cell lib_cell_name
[-input_pin lib_pin_name]
load_type_name
```

Creates a load type, which is identified by a unique *load\_type\_name*. Typically, the load type represents a capacitance value from a library input or bidirectional pin. You can create multiple load types for a PTM model provided you use different `create_ptm_load_type` commands for each load type.

**Note:** The load type can be associated with PTM ports by using the `set_ptm_port_load` command.

### Parameters

|                                                |                                                                                                                                                                                                                                                  |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-lib_cell</code><br><i>lib_cell_name</i> | Specifies the reference cell which will be used to derive the load characteristics.                                                                                                                                                              |
| <code>-input_pin</code><br><i>lib_pin_name</i> | Specifies the name of the input or bidirectional pin which will be used to derive the load characteristics.<br><br><b>Note:</b> When this option is not used, the software randomly selects an input or bidirectional pin from the library cell. |
| <i>load_type_name</i>                          | Specifies a unique name for the load type.                                                                                                                                                                                                       |

### Example

- The following command defines a load type called `stdLoad` for the `INVX1` cell and the input pin `A`:

```
tempus> create_ptm_load_type -lib_cell INVX1 -input_pin A stdLoad
```

### Related Commands

- `set_ptm_port_load`

## create\_ptm\_model

```
create_ptm_model model_name
```

Initiates the creation of a Prototype Timing Model (PTM) model. A PTM model contains preliminary information about the block, such as ports, delay arcs, and timing check arcs.

**Note:** You must save the existing model details using the `save_ptm_model` command before creating another model. This means that you cannot generate multiple models at the same time.

### Parameters

|                   |                                     |
|-------------------|-------------------------------------|
| <i>model_name</i> | Specifies a name for the PTM model. |
|-------------------|-------------------------------------|

### Example

- The following command creates a PTM model named `sample_model`:

```
tempus> create_ptm_model sample_model
```

### Related Commands

- `report_ptm_model`
- `save_ptm_model`

## create\_ptm\_path\_type

```
create_ptm_path_type
[-help]
-type arc_type
-lib lib_name
-lib_cell lib_cell_name
-relative_pin pin_name
-target_pin pin_name
path_type_name
```

Uniquely identifies the worst time arc of the given type between a pin pair for a given library cell when `-target_pin` and `-relative_pin` has been specified. If only either of `-target_pin` or `-relative_pin` is specified, the **software** finds out the worst library arc seen with type as provided with `-type` parameter. If no pin is specified, then the first worst arc with type as specified with `-type` parameter is selected. The created path type name is used later with the `create_ptm_constraint_arc` and `create_ptm_delay_arc` commands to create the reference time arc inside the PTM model. Newly created arc will inherit the rise/fall delay/ slew LUTs after applicable scale specified by `-path_factor` in `create_ptm_constraint_arc/create_ptm_delay_arc` and the unateness property from the reference arc.

### Parameters

|                                      |                                                                                                                                                                                                                                                                                       |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                   | Prints out the command usage.                                                                                                                                                                                                                                                         |
| <code>path_type_name</code>          | Specifies the name to uniquely identify a reference timing arc specification (path type) which can be used for multiple PTM creation later.                                                                                                                                           |
| <code>-type arc_type</code>          | Provides the arc type from which the reference library is to be picked up. This reference library will be used as the reference arc for this path type. Possible type values are: <code>setup</code> , <code>hold</code> , <code>combinational</code> , and <code>sequential</code> . |
| <code>-lib lib_name</code>           | Specifies the reference library name.                                                                                                                                                                                                                                                 |
| <code>-lib_cell lib_cell_name</code> | Specifies the reference cell name.                                                                                                                                                                                                                                                    |
| <code>-relative_pin pin_name</code>  | Specifies the relative pin (that is, reference pin for check arcs and source pin for delay arcs) for picking the reference arc.                                                                                                                                                       |
| <code>-target_pin pin_name</code>    | Specifies the target pin (that is, signal pin for check arcs and sink pin for delay arcs) for picking the reference arc.                                                                                                                                                              |

## Example

- The following command specifies the reference check arc from relative pin `CLK1` to the target pin `D1`:

```
tempus> create_ptm_path_type SETUP_TYPE1 -lib_cell DFFX1 \
-relative_pin CLK -target_pin D1 -type setup
```

## Related Commands

- `create_ptm_constraint_arc`
- `create_ptm_delay_arc`

## create\_ptm\_port

```
create_ptm_port
[-help]
[-clock]
[port_list]
[-type {output | inout | input | internal | clock}]
```

Creates a PTM port for the current model.

### Parameters

|                                                                |                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-help</code>                                             | Prints out the command usage.                                                                                                                                                                                                                                                                           |
| <code>-clock</code>                                            | Specifies that the provided port is a clock port.<br><br>The software allows clock creation at an internal pin of PTM with another internal pin as a source.                                                                                                                                            |
| <code>port_list</code>                                         | Specifies a port names of the type specified with the <code>-type</code> option.                                                                                                                                                                                                                        |
| <code>-type {output   inout   input   internal   clock}</code> | Specifies the type of port to create. You can use one of the following values to specify the type of port: <ul style="list-style-type: none"><li>• <code>output</code></li><li>• <code>inout</code></li><li>• <code>input</code></li><li>• <code>internal</code></li><li>• <code>clock</code></li></ul> |

### Examples

- The following command creates a bidirectional port named `bidiA`:  
`tempus > create_ptm_port -type inout bidiA`

### Related Commands

- `create_ptm_load_type`

## report\_ptm\_model

```
report_ptm_model
[-path_types]
[-ports]
[-delay_param]
[-arcs]
[-arc_type]
```

Generates a report on ports, arcs, and global delay parameter details for the current PTM model. This command must be used after the `create_ptm_model` command and before the `save_ptm_model` command.

### Parameters

|              |                                                                                                                                                 |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| -arcs        | Displays the timing arc details for the current model, such as the input port, output port, and the delay value associated with the timing arc. |
| -arc_type    | Reports the type of arc. When specified, the command output displays the <code>Arc Type</code> column.                                          |
| -delay_param | Displays the global delay parameter details set using the <code>set_ptm_global_parameter</code> command.                                        |
| -path_types  | Reports only the path type details.<br><i>Default:</i> Includes the details of path types created.                                              |
| -ports       | Displays the port details from the current PTM model that were set using PTM commands.                                                          |

### Example

- The following command displays a report on the arcs of the `model1` PTM model:

```
tempus> report_ptm_model -arcs
ModelName : model1
Arc From To Delay PathType PathFactor
--- ---- -- -
refclk_to_spi_fs refclk spi_fs 0.3 - -
spi_fs_to_scan_se spi_fs scan_se 1.0 - -
```

- The following command displays a report on the type of arc of the `model1` PTM model.

```
report_ptm_model -arc_type
ModelName : model1
```

```
DriveType Cell

stdDrive pllclk

PathType Cell Arc Type

```

No path type defined.

- The following command displays a report on the global delay parameters of the `model1` PTM model:

```
report_ptm_model -delay_param
ModelName : model1

DelayParameter Delay

setup -
hold -
clk_to_output -
```

- The following command displays a report on the port details of the `model1` PTM model:

```
report_ptm_model -ports
ModelName : model1

DriveType Cell

stdDrive pllclk

Port Direction BusRange LoadValue LoadType DriveValue DriveType

refclk clock - - - - -
scan_se out - - - - -
spi_fs in - - - - -
```

- The following command displays a report on the global delay parameters of the `dma` PTM model:

```
tempus> report_ptm_model -delay_param

ModelName : dma
DelayParameter Delay

```

```
setup 1.2
hold 1.5
clk_to_output 1.6
```

- The following command reports the path type details for the SETUP\_TYPE1 path type.

```
tempus> create_ptm_model <name>
:
tempus> create_qtm_port -type clock CLOCK
tempus> create_qtm_port -type input IN
:
tempus> create_ptm_path_type SETUP_TYPE1 -lib_cell typ_1.2/DFFX1 \
-relative_pin CLK -target_pin D1
tempus> create_ptm_path_type HOLD_TYPE1 -lib_cell typ_1.2/DFF2X1 \
-relative_pin CLK -target_pin D2
tempus> create_ptm_constraint_arc -from clock_gen_1 -to data_in -setup \
-edge fall -path_type SETUP_TYPE1
```

## Related Commands

- [create\\_ptm\\_model](#)
- [save\\_ptm\\_model](#)

## save\_ptm\_model

```
save_ptm_model
[-help]
[-output filename_prefix]
[-library_cell]
```

Saves the PTM model including the timing arc specifications in the .lib library file format. The file name contains the PTM cell with the pin and bus definitions, and various constraints and delay arcs that are created by `create_ptm_*` command set.

### Parameters

|                                   |                                                                                                                                                     |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| -help                             | Prints out the command usage.                                                                                                                       |
| -library_cell                     | Specifies the reference cell which will be used to derive the model characteristics.                                                                |
| -output<br><i>filename_prefix</i> | Specifies the output file name.<br>If a file name is not specified, the model name defined using the <code>create_ptm_model</code> command is used. |

### Examples

- The following command specifies a PTM model file name:

```
tempus > save_ptm_model -output ptm.lib
```

### Related Commands

- `create_ptm_model`
- `report_ptm_model`

## set\_ptm\_design\_rule

```
set_ptm_design_rule
{-max_transition <max_tran> | -max_capacitance <max_cap> | -max_fanout <max_fanout>}
[-port port_list]
```

Specifies a value for the `max_transition`, `max_capacitance`, and `max_fanout` design constraints. These values can be applied to all the ports or a selected list of ports.

### Parameters

|                                                 |                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-max_capacitance</code><br><i>max_cap</i> | Specifies the <code>max_capacitance</code> value for the ports in the PTM model.                                                                                                                                                                                                                                             |
| <code>-max_fanout</code><br><i>max_fanout</i>   | Specifies the <code>max_fanout</code> value for the ports in the PTM model.                                                                                                                                                                                                                                                  |
| <code>-max_transition</code><br><i>max_tran</i> | Specifies the <code>max_transition</code> value for the ports in the PTM model.                                                                                                                                                                                                                                              |
| <code>-port port_list</code>                    | <p>Specifies a list of PTM port names on which the value specified with the <code>-max_capacitance</code>, <code>-max_fanout</code>, or <code>-max_transition</code> parameters should be applied.</p> <p><b>Note:</b> This parameter allows you to specify a list of patterns for port names using wildcard characters.</p> |

### Example

- The following commands specify a global `max_transition` value of 1.0 for all ports except `trigger`, which will use the `max_transition` value of 1.1:

```
tempus> set_ptm_design_rule -max_transition 1.0
tempus> set_ptm_design_rule -max_transition 1.1. -port trigger
```

## set\_ptm\_global\_parameter

```
set_ptm_global_parameter
-param {setup | hold | clk_to_output}
-value real_number
```

Defines global values for setup check arcs, hold check arcs, or sequential delay arcs across the PTM model. This global value is added to the arc specific delay value. As a result, the final arc's delay is calculated as a sum of the global parameter value and the arc delay specified using the `create_ptm_constraint_arc` or the `create_ptm_delay_arc` command.

**Note:** The global parameters must be specified before defining the first arc in the current PTM model.

### Parameters

|                                                    |                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-param {setup   hold   clk_to_output}</code> | Specifies the name of a global parameter, which can be one of the following: <ul style="list-style-type: none"><li>• <code>setup</code> for setup check arcs.</li><li>• <code>hold</code> for hold check arcs.</li><li>• <code>clk_to_output</code> for sequential delay arcs.</li></ul> |
| <code>-value <i>real_number</i></code>             | Defines a value for the specified global parameter name.                                                                                                                                                                                                                                 |

### Example

- The following command specifies `setup` as the global parameter and assigns the value `1.2` to it:  

```
tempus> set_ptm_global_parameter -param setup -value 1.2
```

### Related Commands

- `create_ptm_constraint_arc`
- `create_ptm_delay_arc`

## set\_ptm\_port\_drive

```
set_ptm_port_drive
-type drive_type
[-input_slew_rise rise_slew_value]
[-input_slew_fall fall_slew_value]
port_list
```

Sets the drive for the output and bidirectional ports. The *drive\_type* specifies the type of cell within the model as drivers on the interface nets. You cannot specify two different drivers for two timing arcs ending at the same output port.

### Parameters

|                                            |                                                                                                                                                                           |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>port_list</i>                           | Specifies the name of the output or bidirectional port.<br><b>Note:</b> This parameter allows you to specify a list of patterns for port names using wildcard characters. |
| -input_slew_fall<br><i>fall_slew_value</i> | Overrides the fall transition value specified with the<br>-input_slew_fall option of the <code>create_ptm_drive_type</code> command.                                      |
| -input_slew_rise<br><i>rise_slew_value</i> | Overrides the rise transition value specified with the<br>-input_slew_rise option of the <code>create_ptm_drive_type</code> command.                                      |
| -type <i>drive_type</i>                    | Specifies the drive type to use for the timing model.                                                                                                                     |

### Examples

- The following command sets the `stdDrive` drive to be used on the output data port `data_out`:  
tempus> set\_ptm\_port\_drive -type stdDrive data\_out

### Related Commands

- `create_ptm_drive_type`

## set\_ptm\_port\_load

```
set_ptm_port_load
-type load_type_name | -value real_number
[-multiply_by multiply_factor]
port_list
```

Defines a load for PTM model ports by either specifying a capacitance value or by using the load type defined by the `create_ptm_load_type` command.

### Parameters

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -type<br><i>load_type_name</i>         | Specifies the load type name created by the <code>create_ptm_load_type</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -multiply_by<br><i>multiply_factor</i> | Specifies the multiplication factor that will be used to calculate the load on the specified ports, as shown:<br><br>Load on port(s) = {(load_value) * (factor)}<br><br>Where: <ul style="list-style-type: none"> <li><i>load_value</i> is the capacitance value derived from the cell name specified with the <code>-lib_cell</code> option of the <code>create_ptm_load_type</code> command when you use the <code>-type</code> option.</li> <li><i>factor</i> is the multiplication factor.</li> </ul> |
| -value<br><i>real_number</i>           | Specifies the value to be used as load/capacitance for the list of ports specified. The value specified with this option overrides the load value that is derived by the <code>-type</code> option.<br><br><b>Note:</b> This option cannot be used with the <code>-multiply_by</code> option.                                                                                                                                                                                                             |
| <i>port_list</i>                       | Specifies the list of input or bidirectional ports that exist in the PTM model defined by the <code>create_ptm_port</code> command.<br><br><b>Note:</b> This parameter allows you to specify a list of patterns for port names using wildcard characters.                                                                                                                                                                                                                                                 |

### Example

- The following command defines a load for the PTM model port `data_in_2` by specifying a capacitance value of 0.15:  
tempus> set\_ptm\_port\_load -value 0.15 data\_in\_2
- The following command specifies a load type called `stdLoad` and a multiplication factor of 2 for

the `data_in` port:

```
tempus> set_ptm_port_load -type stdLoad -multiply_by 2 data_in
```

## Related Commands

- `create_ptm_load_type`
- `create_ptm_port`
